Preliminary Assessment Report
DuPont Chambers Works Complex
Pennsville and Carneys Point Townships, Salem County

Dear Mr. Park and Mr. Faranca:

Enclosed is the Preliminary Assessment Report for the DuPont Chambers Works Complex completed in accordance with N.J.A.C. 7.26E-3.1. Andy, you are getting one hard copy and a complete CD, and Frank, you are getting three copies and a complete CD. This Preliminary Assessment was completed to support the site-wide remedial strategy for the Chambers Works as initially outlined in the DuPont letter to NJDEP dated July 1, 2005, and further refined in the DuPont letter to NJDEP dated September 9, 2005. This site-wide remedial strategy was developed in response to the NJDEP letter dated April 6, 2005 that requested DuPont to address the following two major issues:

- Long-term remediation of the site that includes the following: focused source reduction, treatment or removal of sources (including the use of innovative technologies), optimization of the groundwater recovery system, and enhanced monitoring of internal and boundary ground water wells
- The discharge of contaminated groundwater and surface water to the Delaware River and its tributaries

DuPont developed a geographical information system (GIS)-based conceptual site model (CSM) in the first half of 2006 as an initial step in the Preliminary Assessment process. The GIS-CSM was demonstrated to NJDEP and EPA in August 2006. This comprehensive GIS-CSM was a critical tool in completing the review of available data given the robust operational history and size of the Chambers Works. The GIS-CSM integrates aerial photographs, plant maps, environmental sampling analytical results, historical process data, geologic and hydrogeologic data, and site operational history to allow an evaluation of potential sources and environmental fate and transport of site contaminates.

As a result of the comprehensive evaluation of the Chambers Works Complex, the Preliminary Assessment identified eleven AOCs, which were all located in the active Chambers Works manufacturing area. DuPont recommends additional investigation within the AOCs as described in the report. In general, recommendations were developed to characterize potential source areas and enhance groundwater monitoring throughout the entire Chambers Works Complex as requested by NJDEP in the April 6, 2005 letter. In addition, DuPont is currently completing computer modeling to optimize the groundwater recovery system and is scheduled to report the findings of this evaluation in 2007.

DuPont will submit a Site Investigation/RCRA Facility Investigation Work Plan after EPA and NJDEP review and approve the enclosed PAR. The initial work plan will focus on AOCs at the site perimeter. Obviously, interim remedial measures (IRMs) will be proposed and implemented if justified and appropriate based on findings of the future investigations.

If you have any questions or comments, please email me at **Albert.J.Boettler@usa.dupont.com** or call me at 302-892-0647.

Very truly yours,

Albert J. Boettler

EXECUTIVE SUMMARY

A Preliminary Assessment (PA) of the E.I. du Pont de Nemours and Company (DuPont) Chambers Works Complex (the site), performed in accordance with New Jersey regulations, has identified 11 areas of concern (AOCs) within the boundaries of the site where additional investigation is recommended along with sediment sampling at historical outfalls into surface-water bodies. The comprehensive evaluation of the 122-year site history combined with existing environmental and hydrogeological data further supports the conclusions of the previous conceptual site model whereby site related constituents are effectively contained by the on-site interceptor well system and prevented from migrating towards the surrounding communities[1]. Additionally, no AOCs were identified on off-site properties previously owned by DuPont. Based on the results of this Preliminary Assessment, no exposure to site-related constituents is indicated; therefore, there are no unacceptable risk to human health or the environment.

The PA reported here encompasses the 1,455-acre DuPont Chambers Works Complex located along the eastern bank of the Delaware River in Deepwater, New Jersey as well as off-site properties previously owned by DuPont. The PA was performed in accordance with N.J.A.C. 7.26E-3.1 and as part of the DuPont comprehensive program for long-term remediation developed in conjunction with NJDEP, which was specified in the DuPont letter to NJDEP dated July 1, 2005.

The purpose of a PA is to identify potential areas where contaminant sources are suspected. These suspected areas are considered AOCs. A PA is typically performed as an initial phase of site investigation and prior to implementing any remedial actions. However, DuPont has already completed four phases of the Resource Conservation and Recovery Act (RCRA) Facility Investigation and completed numerous remedial actions. Over the past 15 years, more than $150 million has been spent to investigate and remediate areas of the site. Many of these projects were initiated by DuPont and were facilitated by the cooperative working relationship with the NJDEP and the EPA.

The PA described herein was performed with the use of a Geographic Information System (GIS) tool. The tool was presented to the NJDEP and EPA in August 2006 and was a crucial evaluation tool for the PA. In order to enable a detailed analysis of the abundance of information that characterizes the complex and extensive manufacturing history of Chambers Works, DuPont invested in the development of a comprehensive GIS and accompanying relational databases. The GIS includes digitized site plan maps from 1919 through 2005, 17 aerial photographs between 1940 and 2002, infrastructure features such as historical and current utilities, surface-water drainage, historical shoreline, landfills, current solid waste management units (SWMUs), current and historical outfalls, historical process wastewater ditches and historical internal building trench locations, locations of public water supply wells, and numerous other geographic and geologic information. The GIS is linked to an environmental analytical database and

[1] A small component of shallow groundwater flow toward the Delaware River exists along the western portion of the Chambers Works complex. DuPont is currently conducting additional investigations to assess potential migration of site-related constituents into the river.

a process history database. The analytical database contains the results from more than 19,000 environmental samples collected at about 3,223 locations. The historical process database is based on historical files that were reviewed by 12 retired Chambers Works scientists. A total of 230 file drawers of detailed process/manufacturing data were reviewed and entered electronically into the database. Both the analytical and process history databases are linked to the GIS, which was then used to evaluate and integrate analytical, spatial, and historical data to identify the potentially contaminated areas of concern.

DuPont has committed to a long-term comprehensive remediation program that builds on and integrates the current understanding of the Chambers Works site. The goal of this program is to focus future remedial actions in order to achieve environmental results. Development of the GIS tool, and its continued upgrade, will be used in a systematic process of source identification, evaluation, and testing consistent with NJDEP and EPA regulations.

As a result of the comprehensive evaluation of the Chambers Works Complex history as well as the existing environmental data, the PA identified 11 AOCs, all of which were located in the active Chambers Works manufacturing area. No off-site areas of concern in the surrounding communities were identified through this comprehensive evaluation nor was any expousre to site-related consituents indicated. The Chambers Works manufacturing area was the center of research and development as well as manufacturing of a wide range of products. Manufacturing and support buildings were constructed and frequently converted to meet the needs of production. Previous investigations within this area have indicated the presence of process-related constituents (primarily volatile organic compounds and semi-volatile organic compounds) in soil and groundwater. The PA identified additional suspected source areas for further evaluation.

Areas that warrant further investigation were also identified for the former Carneys Point Works, located in the northern portion of the site. However, these areas were not designated as AOCs. Further investigation of these areas will be conducted as part of the ecological investigation for Carneys Point.

Most of the AOCs in the Chambers Works manufacturing area encompass large manufacturing areas where particular products were produced and are relatively large in area. Nine AOCs are between 20 and 80 acres. Ten of the AOCs are contiguous such that nearly the entire southeastern portion of the site is defined by AOCs.

Although the identified AOCs are large in size, specific potential sources have been identified, such as a known chemical release location or chemical loading/unloading areas, for example. Suspected or known groundwater contamination was also used to aid in defining AOCs. Groundwater may act as a source to downgradient groundwater and potentially to the sediment and surface water in downgradient water bodies through groundwater to surface-water pathways.

Sections of the former process wastewater ditch system are present in ten of the 11 AOCs. Although the majority of these earthen ditch sections have been remediated, there is a potential that soil beneath the former ditches or dense nonaqueous-phase liquid (DNAPL) may be present at depth and acting as a source to groundwater contamination at some locations. High concentrations of SVOCs in some wells that are adjacent to and downgradient of ditch sections support this hypothesis. Given the irregular distribution of ditches and the extensive network of process building trenches associated with the ditch system, defining specific portions of ditches as individual AOCs is not possible at this time.

The AOCs resulting from this comprehensive analysis are as follows:

- AOC 1: Fluoroproducts
- AOC 2: TEL
- AOC 3: Jackson Labs
- AOC 4: Aramids
- AOC 5: Historical Basin Footprint and Ditches
- AOC 6: Dyes
- AOC 7: Elastomers
- AOC 8: Warehouse, Transport and Construction
- AOC 9: Monastral
- AOC 10: White Products
- AOC 11: Former Drainage Ditch

DuPont recommends additional investigation within the AOCs, and the recommendations are presented in this report. In general, recommendations were developed to meet the following objectives:

- Evaluate B Aquifer groundwater quality downgradient of potential sources in areas of the site where insufficient data exists. Assessing groundwater quality in these areas will help to determine whether an area is (or was) a source to groundwater.
- Increase spatial characterization of B Aquifer hydraulic gradients near the site perimeter to confirm hydraulic containment by the Interceptor Well System (IWS).
- Further refine understanding of potential groundwater to surface-water pathways by installing additional perimeter monitoring wells.
- Evaluate soils that may be acting as sources to groundwater by further characterizing the distribution of elevated concentrations.
- Evaluate sediment quality in the vicinity of historical process wastewater outfalls along the Delaware River and Salem Canal.
- Further evaluate soil, sediment and surface water quality in Carneys Point as part of the Ecological Risk Assessment for Carneys Point.
- Refine the location/boundaries of several SWMUs based on review of more accurate aerial photographs and GIS data.

Details regarding the recommended investigations, such as the location and number of wells, and the sampling methodologies, will be provided in subsequent work plans following agency review of this PA.

1.0 INTRODUCTION

This Preliminary Assessment Report (PAR) presents the results of the Preliminary Assessment (PA) completed for the E.I. du Pont de Nemours and Company (DuPont) Chambers Works Complex (the site), made up of the Chambers Works manufacturing area and the former Carneys Point Works, in Deepwater, New Jersey. This PA was conducted in accordance with N.J.A.C. 7:26E-3.1 and reported herein in accordance with N.J.A.C. 7:26E3.2.

1.1 Regulatory Background

The Chambers Works Complex has completed four phases of Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) under the direction of the U.S. Environmental Protection Agency (EPA) and the New Jersey Department of Environmental Protection (NJDEP). The RFI at the site has been phased to evaluate and prioritize solid waste management units (SWMUs) within the site, so that remedial actions can be focused on SWMUs that may potentially present a greater risk to human health or the environment. The phased approach enabled three overlapping sets of objectives to be addressed:

- ❑ Achieve site stabilization.
- ❑ Advance the site through the RCRA Corrective Action Process.
- ❑ Address high priority SWMUs on an accelerated schedule, outside of the phased, RFI process.

At the request of NJDEP, DuPont developed a comprehensive program for long-term remediation at the site and for addressing the potential discharge of contaminated groundwater and surface water to the Delaware River and its tributaries. The overall approach proposed for long-term remediation was to identify significant sources to groundwater and surface water and to evaluate the feasibility of remediating those significant sources. The July 1, 2005 letter to NJDEP included a comprehensive schedule that entailed both long-term and short-term projects. Optimization of groundwater recovery and enhanced groundwater monitoring were also presented in this comprehensive program.

DuPont has completed the first step of this comprehensive program. A geographical information system (GIS) based conceptual site model (CSM) was developed; this model integrates information on the site operational history, physical site features, existing CSM information, and existing environmental data. At the completion of the GIS database development, a presentation on the potential applications of this tool was demonstrated to NJDEP and EPA on August 16, 2006.

The GIS database was then used in the identification of potential source areas for the entire 1455 acres at the site. The initial source characterization efforts focused on the identification of data gaps along the perimeter of the site as well as internal manufacturing and waste management areas. Corrective Measures Studies of the currently identified SWMUs were also integrated into this long-term remediation program. In discussions with NJDEP, it was agreed that the results of the CSM would be provided in a PAR.

1.2 Purpose of the Preliminary Assessment

As stated in N.J.A.C. 7.26E-3.1(a), the purpose of the PA is to identify the presence of any potentially contaminated areas of concern. The comprehensive GIS-based CSM compiled extensive information and allowed the integration of various site-specific data/information including site infrastructure, process history, natural physical features, subsurface geology, hydrogeology, and environmental analytical data. Using the GIS tool enhanced the ability to identify source areas, migration pathways, and data gaps.

This PAR also summarizes the GIS tool created for the site. The revised CSM is presented on a site-wide scale as well as by specific area. Potentially contaminated areas of concern were identified. This report presents the findings of the preliminary assessment and, for areas of the site where data gaps were identified, recommendations for filling those data gaps are provided.

1.3 Report Organization

This PAR addresses the entire Chambers Works Complex, including several off-site locations that are no longer owned by DuPont. The report is broken down into the following sections:

- Sections 1 through 3 provide background, history, and details about the approach and methodology used for the PA.
- Section 4 describes the site-wide evaluation.
- Sections 5 through 20 each describe a focus area (FA). The site was broken down into 16 FAs to facilitate the evaluation of the site. FAs are further discussed in Section 3.
- Section 21 presents the conclusions and recommendations.
- Section 22 contains the references cited in this report.

This report contains the following appendices:

- The first three appendices contain general information – EDR reports, a DuPont document list of all remedial investigations conducted at the Chambers Works site, and additional site history and regulatory background.
- Appendix D contains supplemental information about the site-wide evaluation. This appendix includes aerial photographs and a CD containing Adobe Acrobat pdf files. Each file contains tables specific to a focus area. The naming convention for these tables begins with a code designating the focus area (e.g., “WP” stands for “White Products”). Data included in these tables were previously presented to NJDEP in the relevant reports. Due to the number of tables, electronic submission was necessary to reduce the overall size of this PAR.

- Appendices E through T each describe supplemental information for a FA, including the aerial review for each focus area.
- Appendix U contains a CD with soil management data.

2.0 SITE BACKGROUND AND HISTORY

The 1,455-acre DuPont Chambers Works Complex (the site), made up of the Chambers Works manufacturing area and the former Carneys Point Works, is located along the eastern shore of the Delaware River in Deepwater, New Jersey (see Figure 2-1). The Carneys Point Works operated from 1892 to 1979 and produced smokeless gunpowder, nitrocellulose, and related products. The Chambers Works manufacturing area began producing dye in 1917 and gradually expanded as other product lines were added including Performance Chemicals, aramids, fluorochemicals, motor fuel antiknocks, and polymers. As a result of nearly 120 years of continuous industrial activity, Chambers Works is a complicated site. Historically, the Chambers Works Complex has been involved in the development of roughly 1,200 chemical products.

The site is located along the eastern bank of the Delaware River adjacent to the Delaware Memorial Bridge in Deepwater, New Jersey. The site extends approximately 2.7 miles between Helms Cove to the north and the Salem Canal area to the south.

The site is located in a moderately populated area consisting of light to heavy industry, recreational areas, community-service areas, and residential neighborhoods. Situated south of the site is the Conectiv (formerly Atlantic Electric) Power Plant. East of the site are light industrial, residential, and recreational areas. North of the site lies community service and residential areas. The Delaware River is to the west of the site.

The site lies within the Lowland Subprovince of the Atlantic Coastal Plain physiographic province (Barksdale, et al., 1958). The surrounding topography is gently rolling, with elevations ranging from sea level to 85 feet National Geodetic Vertical Datum (NGVD; 1929). Elevations at the site are typically within 10 feet above sea level.

In the 1960s, groundwater contamination was identified. In response, DuPont installed an interceptor well system (IWS) in 1970. The IWS was designed to collect potentially impacted groundwater and to restrict the off-site migration of groundwater for the protection of human health and the environment. The IWS has operated continuously since 1970, and has been optimized and mechanically upgraded to provide current extraction of more than 1.5 million gallons per day.

2.1 General Site History

As per requirements of a PAR as outlined in N.J.A.C. 7:26E-3.1 (c)(1)(ii)(4), the following paragraphs include a brief description of the past industrial usage of the Chamber Works Complex by DuPont. More detailed process and manufacturing history are presented in Sections 5 through 20 and in Appendix C.

The Chambers Works Complex traces its origins to 1892 when Carneys Point smokeless gunpowder plant was constructed at the northern end of Carneys Point. By 1914, gunpowder-manufacturing operations had extended south into what is currently the Chambers Works manufacturing area. The Carneys Point Works was operational from 1892 to the mid-1970s, producing nitrocellulose, smokeless gunpowder, and other products. In 1917, dye and specialty chemical manufacturing began at what was then called the Dye Works (currently Chambers Works manufacturing area). Refrigerant (Kinetic or *Freon*®) and tetraethyl lead (TEL) production began in the 1920s, followed by aromatic chemical manufacturing in the 1940s. By the 1960s, Chambers Works began elastomers production.

As chemical manufacturing areas expanded, low-lying areas were filled in with river dredgings and other fill material to form a foundation for further development. By the late 1970s and early 1980s, the explosive and dye manufacturing divisions were discontinued, leaving only chemical manufacturing. Most of the Carneys Point buildings were razed by 1979, leaving behind only building foundations.

Historically, the Chambers Works Complex has been involved in the development of more than approximately 1,200 chemical products. The following is a list of some of the major manufacturing areas, past and present, and some of their associated process chemicals (DuPont, 1998).

2.1.1 Carneys Point Powder Plants

The plants operated from 1892 to 1979 and consisted of Plants 1, 2, 3, and 4 in the early 1900s. The plants produced nitrocellulose and gunpowder. The materials involved in production included ether, amines, plasticizers, nitrotoluenes, nitroglycerin salts, nitric acid, and sulfuric acid. Off-quality nitrocellulose was the primary waste from this area.

2.1.2 Dye Works Plant (Chambers Works Manufacturing Area)

Dye production operated between 1917 and the early 1980s producing more than 700 different dyes:

- ❑ Dye Manufacturing: This manufacturing division consisted of the following seven areas, each producing sludges and nitrobenzene wastes:
  - Azo Colors: This manufacturing division used organic mercury, amino constituents, benzene, phenols, acids, aniline, toluidine, sulfur, and naphthalene.
  - Basic Colors: Chemically, the products for this manufacturing division included primarily basic and acid dyes of the triarylmethane series and azine series.
  - Sulfur Colors: This manufacturing division used sulfur and sodium sulfides; sulfur black was the first dye produced at the Dye Works, starting in 1917.
  - *Ponsol*®:This manufacturing division used sodium hydroxide, sodium hydrosulfide, aluminum chloride, and sulfuric acid.
  - Monastral® Colors: This manufacturing division used blue and green pigments. The manufacturing operations were a section of the *Ponsol*® area organization and used similar chemicals.
  - White Products: This manufacturing division involved the use of aromatic hydrocarbons, chlorinated aromatics, polymers, elastomers, fibers, and anilines.
- ❑ Indigo Heavy Chemicals Area: This area began operation in 1917, producing indigo dye, sulfuric acid, and chlorine. Other chemicals associated with this area

included sodium hydroxide, hydrochloric acid, ammonia, sodium, sulfur, benzene, nitrobenzene, nitrotoluene, chlorobenzene (CB), methylamines, and ethyl chloride.

- Fluorochemicals Production Area: This area produces *Freon*® products. It began operations in the 1920s and manufactured fluorinated hydrocarbons from hydrofluoric acid, sulfuric acid, hydrochloric acid, carbon tetrachloride, fluorospar (solid), antimony, pentachloride catalyst, and perchloroethylene (PCE). DuPont has phased out chlorofluorocarbon (CFC) production and replaced it with the *SUVA*® product line, which includes hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs).
- Motor Fuel Antiknock Production Area: This area produced motor fuel antiknock compound (MFAC), which contained tetrethyllead (TEL) and tetramethyl lead from sodium, ethylene, methanol, methyl chloride, and ethyl chloride. The lead alkyls are the primary waste from this area. TEL production began in the 1920s and was discontinued in the spring of 1991.
- Petroleum Chemicals: This manufacturing area produces oil additives. Organic amines and methacrylate polymers are made in this area.
- Polymer Products Manufacturing Area: This area produces *Hylene*®, *Hytrel* ®, plastics, and Viton® elastomers using organic isocyanates, phosgene, dinitrotoluene, and hydrochloric acid.
- Aromatics and Specialty Chemicals: This manufacturing area began production in the 1940s and is still one of the primary manufacturing areas. Materials involved in this area include petroleum hydrocarbons, acids, solvents, inorganic constituents, and aromatic hydrocarbons.

2.1.3 Property History

Per N.J.A.C. 7:26E-3.1(1)(ii) (1) through (3), the PAR must include without limitation the names of all the owners and operators, as well as dates of ownership and dates of operation of each operator from the time that the site was naturally vegetated. The following section contains a general summary of the property history associated with the Chambers Works Complex. Property history details are provided in Appendix D. This appendix contains the DuPont Chambers Works real estate inventory map (#2506) and identifies all conveyances, easements, or agreements associated with the property from 1915 to present. Property history before 1915 is documented in DuPont Chambers Works History 1891-1958, dated 1978. Individual focus area history sections describe in more detail whether additional operators are/were operating at the site.

From 1685 to 1891 the area currently identified as the Chambers Works Complex was used for farming or was unused wetlands or tidal marshes. There is no information on the types of agricultural operations that were conducted in the area. On July 19, 1891 The DuPont Powder Company purchased the Thomas Carney farm and constructed the Carneys Point Works. DuPont purchased additional parcels of adjacent land as the Carneys Point Works expanded between 1891 and 1915. These additional parcels were consolidated into the contiguous Carneys Point Works that extended from Helm's Cove to Salem Canal.

From 1915 to 1918 portions of the Carneys Point Works in Deepwater Point were conveyed from the DuPont Powder Company to the DuPont Chemical Company for the construction of the Deepwater Dye Works. Between 1917 and 1927, additional parcels were purchased by the DuPont Chemical Company as the Deepwater Dye Works expanded. These additional parcels included a residential community along the Delaware River north of the Salem Canal known as Fenton's Beach.

From 1927 to present, the contiguous property identified as the Chambers Works Complex has been owned and operated by DuPont. There is no operational information available concerning previous agricultural or residential land use activities prior to the DuPont purchase of individual properties.

2.2 Current Conditions and Manufacturing

Approximately 650 acres of the Chambers Works Complex are currently developed. The Chambers Works Complex produces approximately 600 products using about 1,500 processes in 44 manufacturing buildings. The manufacturing areas at Chambers Works currently include the following:

- ❑ Organic intermediates and aromatics
- ❑ Petroleum chemicals
- ❑ Fluorochemicals
- ❑ Polymers and elastomers
- ❑ Specialty chemicals
- ❑ The RCRA-permitted secure landfill, also known as the Secure C Landfill, which is located north of Henby Creek and the wastewater treatment plant (WWTP).
- ❑ An electric cogeneration facility and gas production facilities run by third parties, which are located within the Chambers Works Complex

2.3 Manufacturing History

The general manufacturing history at the site is described in Appendix C. Details about specific process histories are described in each focus area section, as needed.

2.4 RCRA Corrective Action Regulatory Background

The Chambers Works Complex is subject to a variety of federal and state environmental regulations. The Chambers Works RCRA corrective action program is under the jurisdiction of the United States Environmental Protection Agency (EPA) as a result of the 1984 Hazardous and Solid Waste Amendments (HSWA). A chronological list of major documents and permits related to the corrective action program are summarized below.

2.4.1 Administrative Consent Order, 1984

A New Jersey Department of Environmental Protection (NJDEP) Administrative Consent Order (ACO) was issued in 1984 and later amended in 1988. This ACO required DuPont to implement remedial action at the A, B, and C Basins and the Process Water Ditch System (PWDS), which are SWMUs 14, 15, 16, and 17, respectively. These SWMUs were investigated, remediated, and closed in accordance with the NJDEP ACO, New Jersey Pollution Discharge Elimination System-Discharge to Groundwater (NJPDES-DGW) permit, and approved closure plans. The Remedial Action Report for the C Basin closure was approved by the NJDEP on October 10, 1995. The Remedial Action Report for the A/B Basin closure (except for the A Basin vault) was approved by the NJDEP on June 26, 1997. The Remedial Action Report for the PWDS was approved by the NJDEP on December 2, 1997. The A Basin vault received material from the SWMU 56 (ODCB in B Ditch) Interim Stabilization Measure (ISM), the SWMU 5 ISM and material from the SWMU 52 ISM. The A Basin vault was closed in October 2006. A closure report will be submitted to NJDEP in 2007.

2.4.2 Hazardous and Solid Waste Amendments Permit, 1988

The EPA issued a HSWA permit (No. NJ002385730) to Chambers Works effective November 7, 1988. The HSWA permit requires DuPont to determine the nature, extent, and migration rate of hazardous waste and/or hazardous constituents in soil, groundwater, surface water, subsurface gas, and/or air at any SWMU regardless of the time that the waste was placed in the unit, and to develop corrective action for any releases as appropriate.

2.4.3 Draft RFI Work Plan, 1989

A Draft RFI Work Plan was submitted to the EPA and NJDEP in 1989. The work plan was not implemented. In a July 1992 meeting with the EPA, a decision was made that the proposed work plan was out of date and that DuPont would submit a Current Conditions Report to provide an update of site activities since the Draft RFI Work Plan had been submitted.

2.4.4 Current Conditions Report, 1992

DuPont submitted a Current Conditions Report to the EPA dated December 18, 1992. The primary purpose of this report was to summarize the existing data on the SWMUs and to present additional environmental information collected at the site since 1989 when the Draft RFI Work Plan was submitted.

DuPont received comments on the Current Conditions Report from the EPA and NJDEP on March 25, 1993. Included in the EPA review was a request for a new Phase I RFI Work Plan.

2.4.5 HSWA Permit Renewal Application, 1993

On May 7, 1993, DuPont submitted an application to the EPA for renewing the Chambers Works HSWA permit, six months prior to the November 7, 1993, expiration date of the existing permit. The Regional Administrator has not issued a new HSWA permit. Therefore, in accordance with 40 CRF 270.51, the 1988 HSWA permit remains in effect until a new permit is issued.

2.4.6 Phase I RFI, 1993-1995

DuPont prepared a Phase I (June 1993) and Phase IA (August 1993) RFI Work Plan, which EPA conditionally approved in December 1993. The Phase I RFI was implemented in 1994 and 1995.

DuPont submitted the results of the Phase I RFI in a May 1995 report. The Phase I RFI Report recommended the following activities for the Phase II RFI:

- Groundwater sampling to be more focused on the deeper aquifers
- Dense non-aqueous phase liquids (DNAPL) investigation focused in areas of potential migration as identified in the Phase I Investigation
- Investigation of twelve SWMUs

2.4.7 Phase II RFI, 1996-1998

DuPont prepared a Phase II RFI Work Plan (May 1996) and a Revised Phase II RFI Work Plan (November 1996). EPA and NJDEP approved the Revised Phase II Work Plan in 1997. The Phase II RFI was implemented in 1997 and 1998.

DuPont submitted the results of the Phase II RFI in the October 1998 report. The Phase II RFI report recommended the following activities for the Phase III RFI:

- B Aquifer Tidal Study
- Continue investigation at three SWMUs
- Characterization of five SWMUs

2.4.8 Phase III RFI, 2000-2002

DuPont prepared a Phase III RFI Work Plan (April 2000) and submitted subsequent correspondence addressing Agency comments. EPA and NJDEP approved the Phase III Work Plan in April 2001. The Phase III RFI was implemented from May through September 2001.

DuPont submitted the results of the Phase III RFI in the April 2002 report. The Phase III RFI report recommended the following activities:

- Provide additional investigation of four SWMUs.
- Conduct ISMs at three SWMUs.

2.4.9 SWMU 8, 2003-2004

DuPont prepared two work plans for the 2003 Test Pit activities and for the 2004 Remedial Investigation (RI) activities and submitted subsequent correspondence addressing agency comments. The EPA and NJDEP approved both work plans. The SWMU 8 RI activities were implemented from May to September 2004. DuPont submitted the results of the field activities in a report dated February 15, 2005.

2.4.10 Environmental Indicator CA725, June 2004

In June 2004 EPA determined that Chambers Works met the Government Performance and Results Act criteria of Environmental Indicator CA 725, current human exposures under control.

2.4.11 SWMU 52, July 2004

DuPont prepared a Remedial Action Selection Report (RASR) for proposed Interim Stabilization Measures (ISM) at SWMU 52 and implemented stabilization activities starting in the summer of 2006. A more detailed description of the SWMU 52 activities to date is provided in the Carneys Point FA (see Section 20).

2.4.12 Environmental Indicator CA750, September 2004

In September 2004 EPA determined that Chambers Works met the Government Performance and Results Act criteria of Environmental Indicator CA750, migration of contaminated groundwater under control.

2.4.13 Phase IV RFI Phase IV RFI and Phase IV RFI Supplemental

A Phase IV RFI RCRA Report was submitted to the EPA and NJDEP on April 22, 2005. The report consisted of three sections: investigation of five individual SWMUs, a baseline ecological evaluation (BEE), and an E Aquifer hydrostratigraphic study. The report recommended some additional delineation and evaluation for specific SWMUs, which is currently being completed under the Phase IV RFI Supplemental Work Plan. A report of findings will be submitted to the agencies in the first half of 2007.

The results of the BEE indicated that additional ecological investigation was necessary. With agreement from NJDEP, the BEE report was separated from the Phase IV RFI documentation and will follow its own timeline for completion. A revised independent BEE was submitted to the NJDEP in September 2006. An ecological investigation work plan will be delivered to the NJDEP in the 1st quarter 2007.

The overall key conclusion of the E Aquifer hydrostratigraphic study was that the E Aquifer appears to be impacted only where leaky well casings allow downward migration. Select E Aquifer wells were abandoned in 2006 with concurrence with NJDEP, and information concerning these abandonments will be submitted as part of the Phase IV RFI Supplemental Report.

2.5 Environmental Permits

In accord with NJDEP Technical Regulations N.J.A.C. 7:26E-3.1(c)(4) (xii), all federal, state, and local environmental permits (including permits for all previous and current owners or operators, applied or received, or both) for the site need to be identified. The Chambers Works Complex is subject to a variety of federal and state environmental regulations and permits, and during various remedial activities, numerous permits have been received. The specific permits for remedial actions will not be listed; instead the reader is referred to the existing remedial reports for details. The site-wide permits that are currently in effect are as follows:

- ❑ Hazardous and Solid Waste Amendment (HSWA) Permit
- ❑ Secure C Landfill Permits
- ❑ NJPDES-Discharge to Groundwater Permits
- ❑ NJPDES-Discharge to Surface Water Permit
- ❑ Water Allocation Permit
- ❑ NJDEP Title V Operating Permit
- ❑ Other Environmental Permits

For details about each permit, see Appendix C.

2.6 Regulatory Background on the RCRA Remedial Facility Investigation Process under the HSWA Permit

In accordance with the N.J.A.C 7:26E-3.1(c)(4)(ix), the PAR must list all remedies previously approved by NJDEP in a remedial action work plan. DuPont maintains stabilization of the site both by interim stabilization measures (ISMs) and operation of the IWS. ISMs have been implemented at SWMU 5 and SWMU 43, SWMU 52, SWMU 56 (Aramids Pond), SWMU 56A, and SWMU 45-9 (footprint of proposed Landfill D). DuPont also has implemented a site-wide non-aqueous phase liquid (NAPL) study and recovery program to address recoverable amounts of NAPL when detected. More details concerning the current site strategy are provided below.

2.6.1 SWMU Investigation Status

According to the EPA May 1994 RCRA Corrective Action Plan (Final), the objective of a corrective action program is to “evaluate the nature and extent of the releases of hazardous waste or constituents; to evaluate facility characteristics; and to identify, develop, and implement an appropriate corrective measure or measures to protect human health and the environment.”

The Corrective Action Plan further states:

> ”While final cleanup remains the long-term goal of the corrective action program, the RCRA Implementation Study (RIS) recommended more frequent use, where appropriate, of interim/stabilization measures in early stages or corrective action

> to achieve near term environmental protection at facilities with the most serious problems. This approach, which may also be appropriate during later phases of the process, emphasizes controlling sites by stabilizing identified releases to prevent the further spread of contamination and degradation of the environment."

The DuPont Chambers Works corrective action process during Phases I through IV RFI has focused on characterizing and stabilizing the site with the emphasis on the site perimeter. The RFI process at Chambers Works has been phased to evaluate and prioritize SWMUs within the site, so that remedial actions can be focused on SWMUs that may potentially present a greater risk to human health or the environment (see Table 2-1 and Figure 2-2). The phased approach enabled three overlapping sets of objectives to be addressed:

- ❑ Achieve site stabilization.
- ❑ Advance the site through the RCRA Corrective Action Process.
- ❑ Address high priority SWMUs on an accelerated schedule, outside of the phased RFI process.

Overall, the site strategy is to achieve stabilization of the site such that there are no unacceptable risks to human health or the environment. Stabilization is achieved when all the potential exposure routes for site constituents are controlled or remediated. Future work at Chambers Works under RCRA will start with the development of corrective measure studies in support of remedial alternative evaluations and selection starting with the SWMUs with the greatest potential impact to groundwater (e.g., SWMU 8).

2.6.2 Interceptor Well System

DuPont maintains stabilization of the site groundwater through the use of the IWS and the implementation of ISMs. The IWS is the primary method of maintaining site stabilization at Chambers Works. It consists of three primary and three backup recovery wells and is operated in accordance with NJPDES-DGW Permit No. NJ0083429. Currently, the IWS consists of six wells at the interior of the site to recover groundwater from the C and D Aquifers (see Figure 2-3). The IWS has operated since 1970 and is currently pumping and treating a monthly daily average minimum of 1.5 million gallons per day (1.5 mgd) of groundwater to achieve control. Potentiometric contour maps, supplemented with modeling, have demonstrated that all of the impacted groundwater at Chambers Works is contained by the IWS in the C, D, and E Aquifers. Additional modeling has shown that the small percentage of impacted groundwater in the B Aquifer that migrates off-site does not pose an unacceptable risk to human health and the environment (DuPont, 2004).

DuPont will continue to use the IWS to maintain stabilization. Previously, DuPont concluded that additional steps could be taken to improve the groundwater quality at the site. Specifically, potential areas are being evaluated where additional sources to groundwater – in addition to the DNAPL recovery program – may be remediated. DuPont also is evaluating ways in which groundwater pumping may be reduced to better manage groundwater resources, while still maintaining containment of affected groundwater.

DuPont expects to submit a groundwater modeling and evaluation report to the NJDEP in mid 2007.

Contamination of groundwater in the surficial aquifers at the Chambers Works Complex has been recognized for some time. Under various regulatory programs, DuPont has been working with the NJDEP and the EPA to identify sources of contamination, implement corrective actions where needed, and improve or replace systems that cause or could cause releases to groundwater. The *Current Conditions Report* (DuPont, 1992) and the *Phase II RCRA Facility Investigation Report* (DuPont, 1998), Phase III and Phase IV RFI provide detailed descriptions of the ongoing investigations of potential sources of contamination and the current groundwater quality across the site.

As mentioned, the IWS currently includes six recovery wells in the central area of the site that withdraw an average minimum of 1.5 million gallons per day. The removal of this groundwater induces flow gradients toward the interior of the site and, consequently, helps ensure that groundwater in the underlying B, C, and D Aquifers does not leave the site. Groundwater elevations are monitored semi-annually in over 300 wells, and groundwater elevation contour maps are created from the resulting data.

Well measurement data have documented the zones of influence of the IWS wells (cones of depression). The design of the system requires continual refinement as additional information about the hydraulic properties of the subsurface materials is developed and as the activities in various areas of the site change. These data are used to evaluate the effectiveness of site-wide groundwater containment and are presented in semiannual summary status reports on April 30 and October 31 of each year. The reports are submitted in accordance with Part IV.F of the NJPDES-DGW Permit No. NJ0083429 and provide results of groundwater monitoring programs and the status of corrective action programs.

2.6.3 Classification Exception Areas

Pursuant to the February 1, 1993, Groundwater-Quality Standards (N.J.A.C. 7:9-6 et seq.), the NJDEP has designated two classification exception areas (CEAs) for the groundwater beneath the Chambers Works Complex in Pennsville and Carneys Point Townships (see Figure 2-4). The Department based this decision on the following:

- The groundwater at the site is hydraulically controlled by groundwater recovery systems necessary for the protection of human health and the environment.
- DuPont signed an Administrative Consent Order with the Department in which DuPont committed to remediating the RCRA land disposal units at the site.
- DuPont is complying with their EPA Hazardous and Solid Waste Management Permit, which requires DuPont to identify and reduce the sources of contamination on-site.
- Use of the property for industrial purposes is expected to continue in the future.
- The constituent standards have been exceeded for a number of constituents at the site.

A Classification Exception Area (CEA) has the effect of suspending the designated uses [potable Class IIA Quaternary Aquifer and Potomac Raritan Magothy (PRM) Aquifer System beneath the site] and constituent standards in the indicated area of operation of the recovery systems for the duration of this NJPDES-DGW Permit. The southern portion of CEA 1 includes groundwater beneath Lots 1,2,3,4 & 5, of Block 301, Pennsville Township, Salem County. The northern portion of CEA 1 includes Lots 1, 2, and 3 of Block 185 and Lot 5, Block 193 of Carneys Point Township, Salem County to a depth of approximately 200 feet. CEA 1 now includes the ball fields in Lot 5, Block 193. CEA 2 includes groundwater beneath Lots 1 and 2 of Block 185, Carneys Point Township, Salem County, to a depth of approximately 200 feet. The NJPDES-DGW Permit No. NJ0083429 lists the compounds for which the constituent standards are suspended for the duration of the permit.

3.0 EVALUATION APPROACH AND METHODOLOGY

This section describes the approach and methodology used to identify potentially contaminated areas of concern at the site that warrant additional investigation. As described below, the approach and methodology included developing a comprehensive Geographic Information System (GIS) and accompanying databases of site analytical data, historical process information, and spatial data. This GIS was used as an investigative tool. Other elements of the approach included the division of the site into focus areas and implementing a conceptual model of migration pathways for use as a basis for integrating analytical data with site process information. This approach was used for all areas of the site, including areas not previously designated as SWMUs or areas of concern (AOCs) under the RCRA CA program and the ACO with NJDEP (1984, 1988). The final step in the approach was evaluation of the site as a whole as described in Section 3.8.

Importantly, Section 3.3 provides a description of the New Jersey Technical Requirements for Preliminary Assessments, and it references where each required element is presented, or how it was implemented, in this report.

3.1 Background

DuPont has committed to a long-term comprehensive remediation program that builds on and integrates the current understanding of the site. The goal of this program is to focus future remedial actions in order to protect human health and the environment. As part of this long-term focus, DuPont proposed to follow a systematic process of source identification, evaluation, and testing consistent with NJDEP regulations. EPA RCRA CA, NRC and ITRC publications were consulted for additional technical guidance. As part of this systematic process, DuPont developed a geographical information system (GIS) that enables integration of site operational history, analytical data of environmental sampling, and spatial data. The GIS was used to as the main tool for integrating and evaluating the data.

The objectives of this evaluation are to answer the following questions:

- What are the historical site conditions and practices that may have resulted in releases to the environment and what constituents are likely to have been released?
- What are the pathways through which constituents may have been or are transported into environmental media (receptor media)?
- What are the potential impacts of these constituents on receptor media?
- What additional investigations are needed to evaluate the presence and/or effects of known or potential historical sources?

In the following sections, the approach used to perform the evaluation is outlined first; development of the GIS tool and database are described second; the methodology used to implement the approach is described third.

3.2 Approach

Numerous investigations have been performed at the site, including four phases of RFI and other area-specific investigations and remedial measures. As part of these investigations, contaminant sources have been identified and remediated, as appropriate. The work performed as part of this PA was executed for the entire site and for areas that were not previously evaluated in detail. Specifically, the identification of potential sources and impacted receptor media described in this report was performed by executing the following tasks:

- Developed a GIS and accompanying analytical database for the site. Together, these features constitute the Chambers Works GIS.
- Subdivided the site into focus areas (FAs) based on past production history and for evaluation purposes.
- Developed a conceptual site model of how contaminants migrate from sources to other environmental media (e.g., groundwater, sediment, surface water).
- Identified manufacturing processes (including raw materials, intermediates, products, and wastes) and, to the degree possible, quantified corresponding production rates, based on review of the process history database, literature review, and interviews with site retirees. In addition, the waste disposal methods and waste streams were identified using these information sources.
- Identified potential historical or current contaminant sources and receptor media based on an analysis of soil, sediment, surface water, and groundwater data, process history data and spatial data (site maps, aerial photographs, e.g.), and based on the conceptual model of contaminant migration. This methodology is referred to as a *pathway analysis* in this report.
- Based on the results of the FA evaluations, presented the results and the overall revised conceptual model of potential sources and migration pathways on a site-wide scale.
- Identified areas where additional investigation is recommended in order to confirm the presence of a source and the potential impact to surrounding media.

The approach and methodology were developed such that they satisfy the requirements for a Preliminary Site Assessment, as described below.

3.3 NJDEP Technical Requirements for Preliminary Site Assessment

According to the New Jersey Technical Requirements for Site Remediation (Amendments Feb 3, 2003), subchapter 3, concerning Preliminary Assessment and Site Investigation, the “purpose of a preliminary assessment is to identify the presence of any potentially contaminated areas of concern.” The assessment must be based on diligent inquiry.

Diligent inquiry according to N.J.A.C. 7:26 E-3.1 (c) must include evaluation of the following (bold text indicates where the information is located in this report):

- Historical information including maps, title and deed, site plans and facility as-built drawings, and NJ I-map Geographic Information System (GIS).
  Any aerial photographs and plant layout maps that were found for the site were placed into the Chambers Works GIS which is more fully described in Section 3. Plant layout maps not previously provided to the NJDEP are provided in Appendix D. NJ I-map information was also placed into the Chambers Works GIS.

- Site history from time the site was naturally vegetated including names of all owners, dates of ownership of each owner, and dates of operation of each operator.
  A brief description of the site history and property transfers is described previously in Section 2. Additional information is provided in the figures in Appendix D.

- Past and present production processes, including dates, potential water use, ultimate potential discharge and disposal points and how and where materials are or were received on-site.
  A brief description of historical through current production history is summarized in each focus area and information regarding dates and potential discharge or disposal points, if any, is also noted on the Chemical Process data tables (see Appendix D). Material loading/unloading are discussed in each FA, if applicable.

- All former and current containers, container or bulk storage areas, above and below-ground tanks, above and below-ground waste and product delivery lines, surface impoundments, landfills, septic systems and other structures, vessels, conveyances or units that contain or previously contained hazardous substances, hazardous waste, and pollutants.
  Review of areas of bulk storage and tanks was part of the pathway analysis for each focus area and part of the aerial photograph review summary, which can be found in respective focus area appendices.

- For sites that exceed 2 acres, an aerial photograph history of site must be completed back to 1932 or the earliest photograph available.
  Individual focus area aerial photograph reviews are contained in respective appendices. The earliest available aerial photographs dates to 1940.

- Any data or information concerning known discharges that have occurred on the site.
  The site currently maintains a database as part of its spill control plans and is submitted to the NJDEP. In addition, a phase I type of outside vendor database review of releases was completed and downloaded and placed in Appendix A.

- All Federal, State and local environmental permits including permit identification number, application date, date of approval, denial or status, permit expiration

date.
Permits are described in Section 2.5 and in Appendix C.

- ❑ All administrative, civil and criminal enforcement actions for alleged violations of environmental laws concerning the site.
DuPont is requesting a variance on summarizing this information at the current time.

- ❑ All areas where non-indigenous fill materials were used to replace soil or raise the topographic elevation of the site, including dates of emplacement.
Areas of fill were noted during the aerial photograph review and are summarized in each focus area as necessary.

- ❑ Remediation activities previously conducted or currently underway at the site including dates of previous remedial actions, and all existing sampling data concerning contaminants at the site.
Remedial activities are summarized in each focus area section.

- ❑ All existing environmental sampling data concerning contaminants at the site.
Data tables were queried from the DuPont Environmental Database (Envista®) for all media, soil, sediment, surface water, groundwater, and non-aqueous phase liquids (NAPL). Tables are included in Appendix D. Soil Management data are also included in Appendix U.

- ❑ Site visit.
DuPont is requesting NJDEP to grant a variance on the requirement of a site visit, due to the fact that personnel who worked on this evaluation and report are assigned by the DuPont Corporate Remediation Group, along with personnel from the Alliance contractor URS-Diamond, to the Chambers Works Complex and visit it on a daily or regular basis.

3.4 Chambers Works GIS

The GIS was built, in part, to help execute the site assessment described in this report. Notably, the GIS stores and handles site data in a way that provides a dynamic tool for integrating analytical, spatial, and historical data in accord with the NJDEP Preliminary Assessment requirements of diligent inquiry. Specifically, it helped to identify potentially contaminated areas of concern.

More generally, the GIS was developed to support strategic decision-making about the site in the future. Besides its use as an investigative tool for the assessments described here, the main goal of developing the GIS was to help update the CSM for the Chambers Works Complex and to facilitate future updates to the CSM as additional spatial and analytical data are collected (e.g., during future investigations, remedial activities, and from ongoing site monitoring efforts). The CSM developed for the Chambers Works Complex reflects the current understanding of historical and existing site conditions, past and current contaminant sources, environmental fate, and transport of contaminants.

Spatial and analytical data are managed with a GIS database and a relational database, respectively. Many sources of data were collected for incorporation into the GIS database, as described in the following sections.

3.4.1 The GIS Database

Information was gathered and evaluated as described below to meet the requirements of the NJDEP Tech Regulations as previously outlined in Section 3.3. The following spatial data were either scanned or digitized and loaded into the GIS database for review by each focus area evaluator:

- Site plan maps from 1919, 1939, 1945, 1952, 1963, 1967, and 2005. From these maps, 860 structures were digitized, and 165 were identified as process buildings.
- Historical and current infrastructure features (e.g., sea walls, bulkheads, surface water drainage, historical shoreline)
- Landfills, surface impoundments, and conveyances
- Current and historical outfalls
- Historical internal building trench locations identified from library archives and ditch locations (26.5 miles of drainage ditches and trenches)
- Utility maps (well water, sanitary water, river water, fire water, and natural gas)
- Current SWMU map (includes 63 SWMUs)
- Historical aerial photographs (dated 1940, 1942, 1943, 1944, 1946, 1951, 1953, 1954, 1956, 1959, 1962, 1964, 1974, 1979, 1995, 2001, 2002)
- Selected NJ IMAP layers (Public Community Water Supply Wells, Coastal Flooding Areas, etc.)
- Potentiometric maps (1999 to 2005) including 612 well locations (369 active and 243 abandoned)
- Geologic Maps (both Isopach and Top of Aquifer Structure)
- Current topographic map

The data collected from these various sources were merged into the GIS using the following procedures:

- Electronic aerial photographs collected from various sources were loaded directly into the GIS because these photographs already were based on the NJ State Plane coordinates; no modifications were necessary before uploading them into the GIS. Historical aerial photographs were scanned into an electronic format and digitally orthorectified and then loaded into GIS. The 2002 aerial photograph of the site is shown in Figure 3-1.
- Scanned map images, such as plant layout maps with no coordinate system, were geo-referenced using the GIS and the 2002 aerial photograph. A minimum of three anchor/reference points (based on sharply defined and known points) were

assigned manually by the GIS operator to the scanned map. The GIS function was then engaged to place the image over the aerial photograph.

- A variety of drawings that originally were in AutoCAD and Microstation formats (based on the Chambers Works plant coordinate system) were converted to the NJ State Plane coordinate system (NAD 83). A coordinate transformation definition was set up between the Chambers Works system and the NJ State Plane system using the Tralaine (Version 5) program. The maps were then loaded as different layers in GIS.

Senior project personnel completed QA and review of the loaded GIS layers using comparison and cross-verification review techniques so as to check and verify correspondence between the original data and the derived data stored in the GIS. As part of building the GIS database, each layer (such as an aerial photograph) has a set of associated meta-data to ensure that the original source of the derived data sets is documented.

3.4.2 Environmental Analytical Database (Envista)

Environmental data are stored in the Environmental Database using the software Envista®. The database is the repository for all sample data collected at the site, and it includes two types of analytical data: qualified analytical data and soil management program data.

Qualified Data

- Total data set: 586,741 results in 19,260 samples from 3,223 locations
- Soil: 2,398 samples from 1,176 locations
- Groundwater: 8,782 samples from 716 locations
- Surface Water: 668 samples from 167 locations
- Sediment: 191 samples from 106 locations

The locations of soil samples, monitoring wells, surface and sediment samples are shown in Figure 3-2 through Figure 3-5.

The data in the database have been submitted to NJDEP in HazSite data deliverables in their respective original reporting documents.

Soil Management Data

From the early 1980s to present, soil analytical data have been generated as part of the soil management program on the site. Excess soil resulting from excavations and construction activities were sampled, mainly as composite samples, and analyzed for specific analytes. Concentrations were then compared to screening values to determine if these soils were acceptable for on-site reuse or disposal. In many cases, composite samples were collected from temporary holding containers that contained soil collected from different locations, and the analytical methods are not consistent for all samples. Therefore, soil management data provide qualitative to semi-quantitative information about analyte concentrations in soil, so the data are not suitable for determining potential areas of concern and subsequent risk management decisions. As a result, the soil management data (also known as soil reuse data) were evaluated and compiled for this report although the emphasis was placed on the discrete sample analytical data that were collected under the RCRA program investigations.

3.4.3 Historical Process Database

Process data from historical files were reviewed by 12 retired Chambers Works scientists. A total of 230 file drawers of detailed process/manufacturing data were reviewed. These hard copy data were entered into the historical chemical database using a standard template to ensure completeness and accuracy. The database is linked to the GIS tool.

A total of 2,463 raw materials/intermediates/products/wastes were identified as a result of this process. In addition, 433 product lines (batch, continuous, pilot scale) were identified.

3.5 Focus Areas

The process for evaluating the site must consider its size, its long and complex manufacturing history, its extensive list of raw materials, intermediates, and products, as well as the voluminous existing documentation about the site. A summary of the data and information evaluation pursuant to N.J.A.C. 7:26E3-1(c)1vii, vii, ix, and x is required to be presented by area of concern and all phases of work for a particular area of concern need to be integrated into a single discussion of that area. DuPont developed the concept of focus areas to satisfy the requirements of an integrated discussion.

To help manage the evaluation process and discussion, the site was divided into 16 FAs. The FA boundaries are approximate, and areas of the site are interrelated, so discussion of one focus area will often refer to aspects of other adjacent focus areas. The 16 FAs are listed here in the order they are presented in the report (Figure 3-6 shows the FAs):

- ❑ White Products
- ❑ Dyes
- ❑ Jackson Labs
- ❑ Tetraethyl Lead (TEL)
- ❑ Fluoroproducts
- ❑ Aramids
- ❑ Triangle
- ❑ Basins
- ❑ SWMU 8
- ❑ Wastewater Treatment Plant (WWTP)
- ❑ Cogeneration (Cogen)
- ❑ Praxair
- ❑ Miscellaneous
- ❑ Current Off-Site Properties (Off-Site)
- ❑ Pharmaceutical
- ❑ Carneys Point

3.6 Conceptual Model of Potential Migration Pathways

As previously stated, the history of operations at Chambers Works spans more than 110 years with continuous changes in site operations. Locations of historical chemical releases and the subsequent fate and transport a chemical complicates the identification of areas of potential concern in this PAR. Existing analytical data focused on SWMUs and other areas of interest. Many of these areas have been adequately characterized and recommended for no further investigation. At the same time, the process history, spatial data, and historical analytical data provide a means to identify areas of potential interest.

Identification of known sources, or identification of potential sources, was performed in an iterative manner by evaluating the process history, spatial data, and historical analytical data in the context of the following conceptual model:

- Organic and inorganic constituents: soils may act as a source for dissolved phase contaminants in groundwater, which can then migrate toward the site IWS or surface water bodies. Transport pathways were evaluated in the B Aquifer only because this shallow aquifer is closest to potential surface sources and is the dominant transport pathway in the subsurface. Transport pathways in the B Aquifer are defined by the groundwater flow directions (see Figure 3-7).
- Historical process wastewater may have impacted surface water and sediment by way of direct discharge to surface water bodies via outfalls along the site perimeter. These discharges could have impacted sediment, and some impacted sediments may still be present even though process wastewater discharges via outfalls was phased out between 1958 and 1975.
- Historical surface sources of liquid waste, either from the historical process wastewater ditches or from waste ponds, may have resulted in migration of dissolved phase or non-aqueous phase liquids (NAPLs) into the shallow B Aquifer. NAPL trapped in shallow soils and DNAPL at depth can act as an ongoing source to groundwater contamination which, as described above, can then migrate by way of groundwater flow toward the site IWS or surface water bodies.
- In some locations, uncertainty exists as to the presence of potential sources and migration pathways towards receptor media. In order to reduce uncertainty, the conceptual model was used along with the data maintained in the GIS to identify potential significant sources and migration pathways and therefore plan for additional investigations.

3.7 Focus Area Evaluations

Six environmental professionals performed the evaluations. All of these evaluators possess the training and experience needed to conduct the evaluations properly and were supported by the information available to them in the GIS, in the Envista database, and from interviews with current and former employees at the Chambers Works Complex.

The evaluators identified process, manufacturing, storage areas, and other associated structures or features within each FA based on reviewing aerial photographs, evaluating building maps, and interviewing employees/retirees. The chemical process database was used to generate lists of raw materials, intermediates, products, and wastes that were associated with the buildings located in each of the focus areas.

Envista was queried for data associated with each focus area. Analytes were compared to applicable criteria and are presented for each focus area by media (groundwater, soil, sediment, surface water, and other as applicable). In some cases, a one-time grab sample of groundwater or surface water was collected. Results of these samples were also summarized in data tables. Summary tables for analytical data were generated from Envista for each focus area for review of the historical investigation results. Analytes included the following: VOCs, SVOCs, pesticides, PCBs, herbicides in ug/L (water) or ug/kg (solids); metals in mg/L (water) or mg/kg (solid); and tentatively identified compounds (TICs). These data are presented in the appendices.

Soil data were compared to both NJDEP Non-residential direct contact soil cleanup criteria (NRDCSCC) and NJDEP Impact to Groundwater (IGW) criteria. Groundwater data were compared to NJDEP Class IIA Groundwater Quality Criteria (GWIIA). Groundwater data from monitoring wells screened in the B Aquifer was used for the assessment, as described in Section 3.6. Sediment and surface-water results were compared to ecological benchmark as outlined in the BEE (DuPont, 2006).

SWMU 8 FA tables were not resubmitted in this report because they were recently submitted in the SWMU 8 RI Addendum Report (2006). In these cases, the reader is referred back to the original documentation for the complete data sets.

3.7.1 Pathway Analysis

To evaluate the FAs for historical or current sources and receptor media, the data were evaluated from two perspectives.

In one approach, process history and material or waste handling areas were identified along with chemicals used in the area. Potential areas of release or potential source areas were identified. If environmental data were available in the area, they were then reviewed for potential impacts from site activities.

In another approach, environmental data were reviewed first and the spatial distribution of contaminants evaluated. By considering groundwater flow pathways or the location of the soil data, potential sources that may have caused the impact were identified. Both of these approaches were performed in an iterative manner.

An analysis was undertaken by reviewing building maps and aerial photographs to identify process buildings with accessory areas (storage tanks, unloading areas). Then, the chemical database was reviewed for chemicals of interest. Chemicals of interest could be identified based on historical process knowledge obtained from documentation or from interview information. The chemicals of interest were then reviewed for their presence in different media (i.e., soil, surface water, sediment, and groundwater) along physical features such as trenches and ditches. Using the GIS, exceedances in various media were plotted. The goal was to evaluate if any other potentially significant sources were identified.

This analysis is summarized in the pathway analysis discussion for each focus area. Additionally, ditches that may be a potential source area are identified in the focus areas; however, because the ditches are considered on a site-wide scale, they are described in the Section 4.3.1.

3.7.2 Recommended Areas for Additional Investigation

Within each focus area discussion, recommendations for additional investigation are proposed where potential sources were identified. The recommendations are based on the assessment of potential sources and pathway analysis. If no further investigation is necessary, justification is provided.

3.8 Site-Wide Evaluation

Finally, findings from the individual focus areas were integrated into a site-wide conceptual model of known and potential source locations, migration pathways, and receptor media. This integrated evaluation was then used to further define areas for future investigation at the site. The recommended investigations within these areas are also presented. The site-wide evaluation is presented in the next section, and it serves as the culmination of the preliminary assessment of Chambers Works Complex. Subsequent sections provide the detailed analyses conducted for each focus area, followed by a summary of conclusions and recommendations.

4.0 SITE-WIDE EVALUATION

This section presents a discussion of site-wide environmental conditions based on an integration of the focus area (FA) evaluations. Also described in this section is the development and utilization of the Chambers Works GIS. The GIS was the main tool used to integrate data within the FAs, and will be used to accurately identify locations of interest in the field. A detailed historical and analytical data review of the FAs within the context of the site was conducted. As a result, the boundaries that define process areas were refined from the initial FA boundaries into eleven AOCs. These AOCs require additional investigation and general recommendations for additional work are presented.

The purpose of a CSM, generally, is to provide a representation of site conditions that show what is known (or suspected) about contaminant source areas and the physical, chemical, and biological processes of contaminant transport. The CSM for the site in this Preliminary Assessment focused on determining potential source areas and migration pathways to media receptors (i.e., groundwater, surface water and sediment). Because of the intent of this Preliminary Assessment, the updated CSM was not extended to identifying complete exposure pathways to human and ecological receptors.

Based on the evaluation of potential sources and refinement of the CSM, DuPont recommends the following additional investigation:

- Evaluate B Aquifer groundwater quality downgradient of potential sources in areas of the site where insufficient data exists. Assessing groundwater quality in these areas will help to determine whether an area is (or was) a source to groundwater.
- Increase spatial characterization of B Aquifer hydraulic gradients near the site perimeter to confirm hydraulic containment by the IWS.
- Further refine understanding of potential groundwater to surface-water pathways by installing additional perimeter monitoring wells.
- Evaluate soils that may be acting as sources to groundwater by further characterizing the distribution of elevated concentrations.
- Evaluate sediment quality in the vicinity of historical process wastewater outfalls along the Delaware River and Salem Canal.
- Further evaluate soil, sediment and surface water quality in Carneys Point as part of the Ecological Risk Assessment for Carneys Point.
- Refine the location/boundaries of several SWMUs based on review of more accurate aerial photographs and GIS data.

4.1 Objectives

The objectives of the site-wide evaluation are as follows:

- Describe the chemical constituents, sources, and impacted media that are prevalent on a site-wide scale.

- Describe the history and potential impact of a primary on-site source that is present throughout the Chambers Works manufacturing area – the historical ditches and outfalls
- Summarize the findings and recommendations of the individual FA evaluations that are presented in Chapters 5 through 20.
- Based on the results of the FA evaluations, define AOCs wherein additional investigation is recommended.
- Present a revised Conceptual Site Model in tabular form that summarizes the primary constituents of concern, known or suspected media of interest, and the primary historical or current sources in each AOC.
- Summarize the recommended additional investigations within each AOC.

4.2 Site-Wide Constituents

In general, there are two classes of contaminants that are prevalent at the site: organic compounds, including volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs), and metals. The most prevalent are SVOCs.

4.2.1 SVOCs

SVOCs are the most common chemical detected in site soil, groundwater, and sediment. These constituents are mainly associated with the manufacturing of dyes and dye intermediates in the southern portion of the site. Some of the most prevalent SVOCs, in terms of their spatial distribution and concentrations measured in soil, sediment, and in the B Aquifer groundwater, are as follows:

- Chlorobenzene
- Nitrobenzene
- Aniline
- 4-Chloroanaline
- 1,2-Dichlorobenzene
- 1,2,4-Trichlorobenzene

Numerous other SVOCs, and some VOCs such as benzene, are also present but at lower concentrations.

Elevated SVOC concentrations in groundwater are present in the former dyes and intermediates manufacturing areas, in the vicinity of sections of the former process wastewater ditches, at the perimeter of the former basins, and at the western boundary of SWMU 8. Even in areas that did not specifically manufacture dyes or related products, such as the TEL area, SVOCs are present in groundwater. Some wells along portions of Salem Canal and the Delaware River contain elevated concentrations of site-related constituents of concern (COCs), indicating the potential for transport of constituents toward surface water through groundwater discharge. Site-related constituents have also been detected in sediments in the Salem Canal.

Although these SVOCs are ubiquitous across the Chambers Works manufacturing area, in the Carneys Point area, SVOCs are generally not detected in environmental media because these compounds were not used or manufactured in the Carneys Point area (see Figures 3-8 through 3-14b).

4.2.2 Metals

Metals are generally detected across most of the Chambers Works manufacturing area in unfiltered groundwater samples. The most common metals, which also exhibit the highest concentrations, are iron and sodium. Iron and sodium occur naturally in the environment. Other metals present at much lower concentrations include lead, arsenic, aluminum, nickel, mercury, and antimony (for example, see Figures 15a through 16b). These metals were typically used as catalysts for various manufacturing processes.

Metals are not generally detected in the deeper aquifers, and a study is currently underway to further evaluate the potential for vertical migration of metals from the unsaturated zone into the B Aquifer at Carneys Point (Phase IV RFI Supplemental Work Plan, DuPont, 2005).

Lead, in particular, is present at elevated levels in the former TEL manufacturing area, at the perimeter of the Basins FA, and in portions of SWMU 8. The presence of lead at these locations is expected given the manufacturing history and disposal practices. Relative to the SVOCs, lead is very immobile and does not appear to be transported by groundwater, as indicated by the absence of dissolved lead at most locations where total lead is detected above the GWIIA (compare Figure 3-15b and 3-15c[2]). Accordingly, dissolved phase lead is not present in perimeter wells. Therefore, it is unlikely that lead concentrations are migrating from groundwater to surface-water bodies.

4.3 Site-Wide Contaminant Sources

The location(s) of site-related constituents in impacted soils and groundwater may be related, in part, to local features at specific processing, storage, or transport areas. These potential sources are identified in the individual focus area sections. A potential source that is present on a site-wide scale is the historical process wastewater ditch system and associated outfalls. Although these features no longer transport or discharge wastewater and have been remediated under the ACO with NJDEP, migration of site-related constituents during historical operations may have resulted in elevated concentrations in underlying soil and groundwater proximal to the ditch system. This site-wide feature is presented below.

4.3.1 Ditches and Outfalls

Figure 4-1 shows the historical network of process wastewater ditches and outfalls. Minor outfalls to the Salem Canal and Delaware River that have historically discharged only stormwater runoff from roadways and parking areas are not shown. The clustered, relatively short ditch sections represent building floor drains/trenches, sumps, and/or

[2] NJDEP requires comparison of only total groundwater analytical results to GWIIA.

pipes that drained to the main sections of the exterior ditches. All ditch and outfall features were imported from other electronic files if available. Features not available in electronic format were digitized from building maps and site-plan drawings. Ditch and outfall locations created in the GIS were compared to aerial photographs, historic plant layout maps, and other drawings to verify accuracy.

General History

From 1917 through the 1980s, process waste handling at the Deepwater Dye Works (Chambers Works) was through a series of open, lined and unlined ditches. Since 1991, all process wastewater has been conveyed to the on-site wastewater treatment via a system of lined sumps, above ground “regional tanks” and an overhead pipeline. Historically, each production building typically had trenches and/or sumps that collected process wastewater. Process wastewater then flowed into a drainage ditch adjacent to the buildings and combined with process wastewater from other buildings and other waters, including sanitary wastewater, cooling water, stormwater, and steam condensate.

According to interviews with retirees, daily facility cleaning included first washing the buildings and equipment with water or solvents and then channeling the effluent and waste materials to the ditches. Site retirees recalled that ditches were almost always flowing and rarely, if ever, dry.

For buildings at the interior of the site, wastewater entered the nearest ditch and flowed through the network of ditches that ultimately discharged to the wastewater settling basin area at the site interior (see Section 12). The settling basin discharged directly to the Delaware River from 1917 to 1958. The basin was upgraded with an outfall structure and pH adjustment in 1958. Additional upgrades since 1958 include the construction of the WWTP in 1975 and the overhead sewer system in 1991.

For some buildings adjacent to the Delaware River, wastewater entered the nearest ditch and flowed directly to the river through the nearest outfall location. There were up to 15 historical outfalls along the Delaware River and Salem Canal that may have conveyed process wastewater directly off-site prior to discharge permitting requirements in1958[3].

Before 1932, the Salem Canal was a tidal water body connecting the Delaware River to the tidal wetlands of Salem Creek. From 1917 to 1932 wastewater from buildings adjacent to the Salem Canal entered the nearest ditch and flowed to the canal through outfalls, or to the wastewater settling basin at the interior of the site. In 1932 DuPont constructed Munson Dam to isolate the canal from the river. DuPont also reconfigured the ditches adjacent to the canal to prevent process waste from entering the Salem Canal. After 1932, the outfalls to the Salem Canal upstream of Munson Dam discharged stormwater and non-contact cooling water only. Engineering controls have been implemented by DuPont to maintain the water quality in the Salem Canal, as it continues to be the primary potable water source for the Chambers Works.

In 1957, DuPont constructed an outfall structure and treatment system for the wastewater basin in accordance with the Federal Water Pollution Control Act (FWPCA). Wastewater

[3] Since 1991, all process-related wastewater has been conveyed to the on-site WWTP through an integrated system of regional collection tanks and elevated pipelines, thus preventing discharges to the environment.

from the basin was pumped into a surge tank and treated with lime to adjust the pH prior to discharge into the Delaware River via the permitted outfall structure 001.

Between 1958 and 1975, process waste outfalls were plugged, and the wastewater was diverted to the wastewater basin via the ditches. During this period process wastewater discharged to the Delaware River through permitted outfall 001 after settling of solids in the basins and pH adjustment. Other outfalls became permitted and continued to be used for stormwater/non-contact cooling water discharge.

In 1972, DuPont reconfigured the basin and ditch system at the Chambers Works and began construction of the WWTP in accordance with the Clean Water Act. As described in more detail in Section 12, the Basins FA was separated into three basins: A Basin, B Basin, and C Basin. In 1974, the ditch system associated with the TEL manufacturing area was diverted to flow into the C Basin, which was constructed as a settling and pre-treatment basin for TEL process wastewater prior to discharge to the A Basin and subsequent treatment in the wastewater treatment plant.

In 1975, the ditch system from the remainder of the plant was further separated to form “A Ditch” and “B Ditch.” Process wastewater was discharged through the A Ditch to the A Basin and then to the WWTP. Some portions of the former process waste ditches were used for stormwater/non-contact cooling water and designated as B Ditch, discharging to the B Basin. The A Ditch and B Ditch were later designated SWMU 17 and SWMUs 56/56A, respectively (see Figure 4-2). The location of ditches (SWMUs 17, 56, 56A), shown in Figure 4-1, is based on as-built drawings and verified in the field during remediation. These field-verified locations of the ditches from the GIS differ from the hand-drawn approximations of the ditch system layout in the early 1990s. A modified map of SWMU 17 and SWMU 56A that more accurately reflects the locations is planned to be submitted in 2007.

In November 1988 (prior to 11/8/88), as required by regulations, discharge of treated wastewater to the B Basin was discontinued. Treated wastewater went directly to the collection tank where it was combined with B Basin non-contact cooling water and stormwater prior to being discharged to the Delaware River through the permitted NJPDES outfall.

Remediation of Ditches

In 1991, the unlined A Ditch was replaced with a 1,300-foot overhead piping system that remains in use. From 1993 through 1996, a large-scale program was initiated to remediate the network of unlined, exterior ditches. Ditch material was removed from the bottom of all ditch sections down to the groundwater table as required by the NJDEP. The sidewalls of the ditch section were sampled approximately 1 foot from the edge of the ditch and analyzed for specific target constituents. In addition, one sample from each ditch section was sampled for Appendix IX parameters and tentatively identified compounds. In areas where sidewall sample concentrations exceeded the A Ditch sidewall soil clean-up criteria, delineation samples were collected 25 feet on either side of the initial sample. Any area of sidewall soil that had constituent concentrations greater than the soil cleanup criteria was removed to a maximum distance of one foot from the side of the ditch.

SWMU 17 was replaced with a system of pipes and asphalt swales. The replacement system is currently used for collection and conveyance of noncontact cooling water, stormwater runoff, and steam condensate to the B Basin. Once the replacement system was installed, the excavated ditch was brought to grade with clean fill and covered with at least 3 inches of gravel.

Figure 4-1 shows the portions of the ditch system where ditch material was removed in compliance with ACO (indicated in green), and those where no removal was required under the ACO (indicated in magenta). Note that most of the relatively short sections shown in magenta are building trenches/pipes rather than open and unlined ditches. As shown in the figure, the majority of the main sections of exterior ditches were remediated, except for the main ditch sections emanating from the Fluoroproducts FA. These sections were not remediated, in part, because sampling of the ditch sediment at some locations showed minimal concentrations of site-related constituents.

Discussion

Some of the post-excavation samples from subsoils beneath remediated ditches and sidewall samples adjacent to ditches contained constituent concentrations above applicable screening levels. Therefore, it is uncertain whether the soils are acting as significant sources of dissolved phase constituents to the B Aquifer groundwater.

DNAPL has been detected in only a few locations across the site. DNAPL is recovered at SWMU 63 along the Salem Canal and in the northeast portion of SWMU 8. However, uncertainty exists at major portions of the ditch system in the Dyes and intermediate areas where chlorinated solvents were used in manufacturing. Evaluation of groundwater data in several monitoring wells near the main section of the PWDS (SWMU 17) indicate the presence of organic compounds between 1% and 10% of total aqueous solubility, which suggests DNAPL is potentially present. Based on this evaluation, additional investigation is recommended in the area of the ditches.

In addition to major ditch segments, elevated concentrations of site-related constituents may be associated with clustered networks of lined trenches in certain process areas. Based on observations made during the extensive ditch remediation program, drains that lead from the building interior to the exterior ditch were mainly constructed of metal pipes, wooden culverts, or concrete-lined culverts. The integrity of these lined trenches is uncertain. Therefore, site-related constituents may also be present in soils near and beneath the clustered network of the relatively short trench segments shown in Figure 4-1.

4.3.2 Groundwater as a Contaminant Source

Groundwater is defined as an environmental receptor by NJDEP. However, because migration of groundwater containing site constituents can potentially impact surface water and sediment, groundwater at the site is itself a potential source. In 1970, DuPont constructed the IWS to capture groundwater and to help prevent off-site migration of groundwater containing site constituents. The IWS has been in continual operation for 36 years, thus maintaining groundwater containment across a majority of the site[4] and removing site constituents from groundwater through the WWTP. Based on an average flow of 1.5 million gallons per day, and analysis of groundwater quality from the IWS wells, the IWS recovers over 200 pounds per day of organic constituents (e.g., ODCB, chlorobenzene, aniline, nitrobenzene, benzene, etc.).

4.4 Site-Wide Media of Interest

4.4.1 Surface Water

Surface-water features in the vicinity of the site include the Delaware River, Salem Canal, Bouttown Creek, and Henby Creek. The potential migration pathways to these media include surface runoff, interaction between surface water and groundwater (i.e., discharge of groundwater to surface water), and discharges from the historical outfalls.

4.4.2 Groundwater

Because the B Aquifer is the shallowest aquifer beneath the site, it is the first aquifer affected by releases. Therefore, analytical data for the B Aquifer was used for this PA, as described in Section 3. Deeper C and D Aquifers contain site-related constituents above GWIIA criteria (but at much lower concentrations than in the B Aquifer) typically near discontinuities in the B/C confining unit and at interceptor wells. The IWS hydraulically contains C and D Aquifer groundwater on-site. These aquifers will be evaluated further as the long-term comprehensive remedial approach moves forward.

In the deeper E Aquifer, one on-site well, N08-M01E (see Figure 2-3), has relatively low concentrations of some site-related constituents. However, as described in the E Aquifer Evaluation as part of the Phase IV RFI (DuPont, 2005), this is believed to be caused by a faulty well casing as based on cement bond logging. Well N08-M01E was to be properly abandoned by a licensed driller in the spring 2006.

4.4.3 Sediment

Sediment in the vicinity of the site includes Salem Canal sediment, Bouttown Creek and Henby Creek sediment, and Delaware River sediment. Sediment samples have been collected in the Delaware River as part of the SWMU 5 and SWMU 52 pre-design investigations. Organic constituents common to the site were present in SWMU 5 sediment samples. Arsenic and lead associated with the site were detected in sediments adjacent to SWMU 52. Sampling results from the Bouttown Creek and Henby Creek in Carneys Point detected metals. Sediment sampling in Salem Canal in the vicinity of SWMU 63 and analysis of recovered DNAPL revealed elevated concentrations of dye-related organic constituents.

[4] Shallow groundwater along the western portion of the site near the Delaware River flows towards the river. This component of groundwater flow is not believed to result in constituent concentrations being discharged to the river above ambient water quality criteria based on modeling. However, additional investigation is currently being performed to further evaluate this flow path.

Sediment investigation and a remedial alternatives analysis is underway at Salem Canal. Additional assessment of sediment in Carneys Point will be conducted under the ecological risk assessment. Sediment sampling is planned in the Delaware River in the vicinity of the historical process wastewater outfalls. This sampling will be performed as part of the Perimeter Investigation that will follow this PAR.

4.5 Areas of Concern (AOCs) and Recommended Investigations

As described in Section 3, the assessment of potential sources and receptor media described in this report was performed in a step-wise approach, the methodology and findings of which are as follows:

- ❑ Based on an initial understanding of the site history, the site was subdivided into 16 FAs that roughly defined areas with similar histories such as manufacturing processes and waste disposal practices. Based on additional research, sub-areas were defined within some FAs, as shown in Figure 4-2.
- ❑ Aerial photographs, site maps, process history, and analytical data were analyzed to identify potential sources and receptor media, and make recommendations of areas for further investigation. As shown in Figure 4-3, DuPont recommends additional investigations across most of the site. It should be noted that for those areas that are currently being investigated or where remedial measures are underway, additional investigation was not recommended based on the findings of this PAR. For example, SWMU 8 is not designated for additional investigations because characterization is complete and a Corrective Measures Study is underway. Carneys Point also was not designated for additional investigation in this PAR because investigations are ongoing or will be performed as part of a separate ecological investigation.
- ❑ As a result of the detailed historical and analytical data review performed as part of this PAR, the boundaries that define different process areas were refined from the initial FA boundaries. Based on this refinement, and on areas at the site that require additional investigation, 11 AOCs were defined, as listed below and shown in Figure 4-4:
    - AOC 1: Fluoroproducts
    - AOC 2: TEL
    - AOC 3: Jackson Labs
    - AOC 4: Aramids
    - AOC 5: Historical Basin Footprint and Ditches
    - AOC 6: Dyes
    - AOC 7: Elastomers
    - AOC 8: Warehouse, Transport and Construction
    - AOC 9: Monastral
    - AOC 10: White Products
    - AOC 11: Former Drainage Ditch

In addition, Delaware River sediments that may have site-related constituents associated with former outfalls are included in the AOC table in Figure 4-4, and sampling of these sediments is recommended.

The table in Figure 4-4 summarizes the updated conceptual site model, as described in Section 4.6, and provides the recommended investigations within each AOC. Specifics regarding the number and locations of sampling and monitoring points are not presented in this PAR. Following receipt and incorporation of agency comments on this PAR, a work plan for additional investigations associated with the site perimeter will be submitted, followed by a work plan for additional investigations associated with the interior of the site.

Recommendations

Additional investigation is recommended in each AOC. In general, additional sampling is proposed to meet the following objectives:

- Evaluate B Aquifer groundwater quality downgradient of potential sources in areas of the site where insufficient data exists. Assessing groundwater quality in these areas will help to determine whether an area is (or was) a source to groundwater. Example sources include the following:
  - Former process wastewater ditches
  - Major loading and unloading areas
  - Areas of waste disposal
  - Suspected areas of residual NAPL or DNAPL accumulations
- Increase spatial characterization of B Aquifer hydraulic gradients near the site perimeter to confirm hydraulic containment by the IWS.
- Further refine understanding of potential groundwater to surface-water pathways by installing additional perimeter monitoring wells.
- Evaluate soils that may be acting as sources to groundwater by further characterizing the distribution of elevated concentrations.
- Evaluate sediment quality in the vicinity of historical process wastewater outfalls along the Delaware River and Salem Canal.
- Further evaluate soil, sediment and surface water quality in Carneys Point as part of the Ecological Risk Assessment for Carneys Point.
- Refine the location/boundaries of several SWMUs based on review of more accurate aerial photographs and GIS data.

4.6 Updated Conceptual Site Model

A CSM is a representation of site conditions, including what is known or suspected about the contaminant source area(s) and the physical, chemical, and biological processes that affect the transport of contaminants through environmental media to potential environmental receptors. The CSM for the site focused on determining potential source areas and migration pathway to media receptors (i.e., groundwater, surface water, and sediment). Because of the purpose of the Preliminary Assessment (PA), the CSM was not expanded to identifying complete exposure pathways for human and ecological receptors.

The Chambers Works CSM has been updated based on the findings of this PA. The updated CSM is similar to the previous CSM, but more distinct potential sources have been identified.

The CSM can be summarized as follows: site-related constituents, mainly organic chemicals such as chlorobenzene, 1,2-dichorobenzene, aniline, nitrobenzene, benzene, and other SVOCs and VOCs related to the manufacturing of dyes, dye intermediates, and elastomers, are present at elevated concentrations in groundwater across the Chambers Works manufacturing area (south of the Carneys Point area). The distribution of site-related constituents is the result of several factors:

- The size of the historical manufacturing area,
- The fact that the manufacturing and use of these organic chemicals were not building-specific but rather changed from building to building over time,
- Releases of chemicals to soil at discrete locations such as a loading/unloading areas, miscellaneous releases near process buildings, and on a larger scale, from the network of earthen process wastewater ditches that transported liquid waste from the manufacturing areas to the basins.

The presence of organic chemicals in groundwater across much of the Chambers Works manufacturing area is due to (1) the use of these chemicals in manufacturing or as solvents and (2) the transport of groundwater caused by large-scale pumping of the IWS since 1972.

Because of these factors, it is impossible to identify all locations where subsurface soil or DNAPL is contributing to elevated levels of constituents in groundwater.

In some cases, chemicals that are specific to particular products are present mainly in those areas where they were produced. For example, carbon tetrachloride is used in the production of flouroproducts and the highest groundwater concentrations are present in that manufacturing area (see Figure 3-13b). Lead is another example: it is present in soil and groundwater mainly in the former tetraethyl lead manufacturing area (see Figure 3-15b). The very low mobility of lead in groundwater is another reason why it is concentrated in this area.

Historically, some process wastewater discharged from the ditches directly to the Delaware River and Salem Canal via outfalls. Hence, sediment may contain site-related constituents near these locations.

The above discussion outlined the CSM that was defined prior to the PA. All of the elements still hold. The primary updates based on the PA are described below.

Additional potential sources and source areas have been identified. These include, for example, soil present beneath clean fill south of the Basins FA and the location of a 100,000-pound discharge of ortho-chloronitrobenzene near the central portion of the manufacturing area (which occurred in the 1980s). Details regarding these and other sources are described in the FA sections. An updated CSM is summarized in tabular format in Figure 4-4 and includes potential sources, potential migration pathways, and media of interest.

A significant aspect of this PA effort is the precision of the CSM that has been established as a result of the GIS system. For example, although contaminant sources already were considered more likely in manufacturing areas with higher production rates, specific locations within the manufacturing areas have been identified precisely by digitizing site maps and aerial photographs. Further, these locations can now be identified accurately in the field. This upgrade will facilitate confirmation of potential sources, such as ditches, by sampling at precise locations. Similarly, the locations of historical outfalls have been mapped and will therefore be used as the basis to define the sediment investigation program as part of the perimeter investigation.

DuPont will continue to update the GIS system by incorporating the results of additional investigations as they are performed. Likewise, the CSM will be refined and will be an excellent tool to help manage and direct future remedial actions.

5.0 FOCUS AREA – WHITE PRODUCTS

Evaluation of the White Products FA indicates that further investigation is recommended near Ponsol #2 (Building 770) and White Products North Bulk Storage area (north of Buildings 149, 152, 788). The proposed investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

The Ponsol #2 Building trench is an area of interest because solvents (e.g., anthraquinone, chlorobenzene, aniline) were used extensively in the production of Ponsol dyes in this building, and wastes were washed into the building trench and out to the process wastewater ditches. Groundwater sampling in the vicinity of these and other former ditches is recommended to assess these features as potential sources of groundwater contamination.

The Borneol House (Building 148) trenches and drainage are of interest because turpentine and other raw materials may have been released to ditches and/or to a former outfall into the Salem Canal. Sediment has not been sampled at that discharge location. Therefore, evaluation of ditches is recommended, as well as sediment sampling in the Salem Canal at the former outfall locations.

The White Products North Bulk Storage area was long used for chemical storage, and releases may have occurred in former loading, and unloading areas to the north of Buildings 149, 152, and 788. Compounds of interest, including 1,2-DCB and chloroaniline, have been detected in shallow groundwater south of former Buildings 149/152.

There are currently no monitoring wells in the northwestern portion of this FA, which is downgradient of the Bulk Storage area and downgradient of a north-south trending ditch that drained the former Dyes manufacturing area. Therefore, groundwater sampling is recommended in this area to assess these features as potential sources to groundwater.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

5.1 Areas of Interest

The White Products FA encompasses about 20 acres in the southernmost section of the site and in the south-southeastern portion of the former Dye Works (see Figure 5-1). The White Products FA is bounded by the Salem Canal to the south, Broadway Road and the Triangle FA to the north, Shinn Road and the Pharmaceutical FA to the east, and Garage Road and the Dyes FA to the west.

Several SWMUs are located within the White Products FA and have been investigated or remediated as part of the Chambers Works RFI program. These areas are shown in Figure 5-2 and are discussed in the History section (see Section 5.2), but they do not require additional evaluation as part of the pathway analysis:

- SWMU 10: Solvent Recovery Unit II
- SWMU 38: Clean Water Injection Well J05-W01E
- SWMU 41-5: Drum Storage Area

The following areas of interest are subject to pathway analysis to determine if additional investigations are necessary:

- Former Ponsol #2 (Building 770): Western Side of Building Loading Area and Interior Building Trench
- Borneol (also known as Bornidol) House Trench and Ditch (Building 148)
- White Products North Bulk Storage Area (north of Buildings 149, 152, 788)

These areas are shown in Figure 5-3.

Based on common processes, history, chemical use, and disposal practices, the White Products FA has been subdivided into two distinct areas (Figure 5-1):

- Southern side: Synthetic Camphor/White Products area included four buildings, used in the early years for the production of synthetic camphor, which were taken over for White Products. White Products used three main buildings in the area, and one is still in use (Building 788).
- Northern side: Ponsol Colors area consisted of one main manufacturing building (770) and one warehouse (588). Two supporting buildings, the Ponsol office and change house, and a laboratory were located across Broadway Road.

As seen in Figure 5-2, White Products Road divides these two areas.

5.2 History

The White Products area started in 1917 with the production of synthetic camphor. In the 1930s, production of various detergents and textile protectants began and continues to the present day. In 1936, DuPont built the Ponsol #2 building (Building 770) north of the detergent/protectant manufacturing area for the production of Ponsol colors. Ponsol color production was discontinued in 1980s when DuPont sold the dye business. The former Ponsol Colors area is now a parking lot.

5.2.1 Synthetic Camphor and Current White Products Area

Before 1917, the White Products FA was open land and bordered on a road (Canal Road) to the residential community known as Fenton’s Beach. Initial construction of the Deepwater Dye Works began in the 1917 with the construction of the Synthetic Camphor buildings. A plant (consisting of four buildings) was built at the Dye Works on the site of the existing White Products operations (Synthetic Camphor and current White Products area). Synthetic camphor was manufactured from 1918 to about 1922. The compounds used in the production of camphor included the following: acetone, sulfuric acid, caustic soda (sodium hydroxide), chlorine, hydrochloric acid, sulfur dioxide, sperm oil, peanut oil, cocoa nut oil, anhydrous isopropanol, and bulk ammonia. A typical off-gas from the methylol stearamide process was formaldehyde fumes (DuPont, 1978). After the camphor operations ceased, several of the buildings built for camphor production were later converted for use by White Products operations.

In the early 1930s, DuPont acquired the Newport Chemical Cosynthetic camphor process and moved operations into a building originally used for the manufacture of TEL and ethyl chloride. This newly developed process started production in 1932 and continued until 1959. Camphor manufacturing went online with a rated capacity of 1.5 million pounds per year (DuPont, 1978). By adding extra manufacturing equipment, production increased to 2.5 million pounds in 1936. The peak production for camphor was 9 million pounds/year in 1944.

In 1949, the process catalyst was changed and camphene was produced in tablet form. In 1950, DuPont installed equipment for this "Zeset" S (Dimethylolethyleneurea) production. The "Zeset" family of products are used in the textile industry for the coating of various fibers and was sold commercially. The material was used to "cross-link" cellulose to impart crease resistance. In 1955, the camphene tablet line was discontinued, and the equipment was sold. In 1959, DuPont discontinued manufacturing of camphene.

The following buildings were used to manufacture camphor:

- Old Camphor Building/Gardinol Building (147): This building operated from 1918 to 1922 and was idle from 1922 to 1932. In 1932, the building was revamped for production and converted to camphene production in 1934.
- Acetyl Building (149): This building completed sulfation of imported Lorol fatty alcohol with chlorosulfonic acid.
- Camphene Building (152): Building processes are not currently known.
- Building 788 (or “A” Building): Construction of this building started in early 1937. This building produced accelerator No. 522, “Aridex” white products, WPX.HW and MR-41 DuPont Plant Spray, “Duponol” MEAW, Retarder W and “Zwinte” A. In 1938, alcohol purification was added to building processes and dipentamethylenethiuram tetrasulfide (“Tetrone” A) was produced.
- Old Borneol House: This building was also referred to as Bordinol (148) and was demolished in 1946.
- MP-Plant (189): This building was constructed in 1947 and 1948, and was idle in 1949.

No data are available for camphor waste disposal practices. Based on disposal practices ascertained from the Dyes FA (see Section 6), it can be assumed that any wastewater produced was most likely released to the closest ditch system. As discussed in Section 4.3.1, process wastewater from buildings adjacent to the Salem Canal may have discharged directly to the canal prior to 1932, at which time the canal became the primary freshwater water supply for the plant.

5.2.2 Current White Products Area

In addition to producing camphor, in 1932 DuPont formed a corporation with Proctor and Gamble (Gardinol Corporation, later renamed Duponol). The Gardinol Corporation manufactured higher alcohols and sulfates for detergents. From 1932 to present, the White Products FA has made a variety of compounds, including detergents, textile finishing agents, water repellents, rubber chemicals, and petroleum chemicals.

Currently, Building 788 (the “A” Building) is the main building for producing protectant chemicals used for treating textiles and nonwoven materials. Approximately 40 products are produced, most of which use several different monomers, with the main ingredients being either ZFAN or ZFM. (Those ingredients are currently produced in the Chambers Works Zonyl® Intermediates Building.)

Based on a process database review, Buildings 149 and 152 were used to produce compounds similar to those in Building 788 (e.g., Zelec®, liquid surfactants). These buildings were demolished in the late 1980s.

Since 1991, the process wastewater from the White Products “A,” “B,” and “D” buildings is pumped to regional collection tanks and then to the on-site WWTP by overhead pipeline.

5.2.3 Ponsol Colors

The Ponsol Colors area primarily produced vat colors and their precursor intermediates from February 1919 until about 1980 when DuPont sold the dyes business. Ponsol Colors was a DuPont trade name for vat colors containing the anthraquinone nucleus; however, early dye history refers to these dyes as anthracene colors. Vat colors are a class of insoluble dyes that are suitable to impregnate into textile fibers. The dyes produced in the Ponsol Color area included “Ponsols,” “Leucosols,” “Lithosols,” “Sulfanthrenes,” “Potamines,” Celanthrenes,” DuPont Anthraquinone colors, and “Latyls” dyes.

The vat colors made in the Ponsol Colors area were developed from a basic chemical building block, the anthraquinone nucleus. Anthraquinone was originally made at the Dye Works from anthracene (coal tars) and later from phthalic anhydride. In 1936 to 1980, Ponsol Colors production was consolidated into the Ponsol #2 Building (770). The Ponsol #2 Building housed intermediates, colors, and standardization sections, and was expanded in 1939, 1941, and 1952 for increased production. The Ponsol #2 Building was razed in the early 1990s.

Based on Chambers Works documentation dating from 1919 to 1958, dye production from 1922 to 1927 ranged from 1 million to 3.6 million pounds per year. In 1939, production was approximately 37.5 million pounds per year. These production numbers increased from 1939 until 1944, reaching approximately 77.8 million pounds per year. Ponsol Colors production then declined through the late 1940s into the 1950s to approximately 51 million pounds per year. No production statistics for the Ponsol Colors manufacturing area are available for the 1960s and 1970s. In January 1980, DuPont announced the sale of 80% of its dye business, and dye manufacturing at Chambers Works continued only to the end of 1980.

Based on interviews with retired plant personnel, the waste from the Ponsol #2 Building was released to the existing floor drains, which connected to the existing site ditch system. In addition, the building foundation or trench was not removed when the building was razed. The Ponsol #2 Building foundation was covered with gravel, and in 2005 was covered with an asphalt parking lot. Because the trenches were concrete lined, they are not considered to be a significant historical source for soil contamination.

5.3 Previous Investigations

The SWMUs identified as part of the RFI within the White Products FA are shown in Figure 5-2 and are discussed here. More detailed descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

5.3.1 SWMU 10 (Solvent Recovery Unit II)

SWMU 10 recovered chlorinated solvents such as chlorobenzene and 1,2-dichlorobenzene (ODBC) in association with the dye manufacturing area including the Ponsol Colors area. The SWMU is approximately 700 square feet and was sampled as part of the Phase I RFI. Samples for soil were analyzed for the following chlorinated solvents: benzene; chlorobenzene; 1,2-dichlorobenzene (ODCB); 1,3-DCB; and 1,4-DCB. No constituents were detected in the samples. This area is currently paved and used for truck parking. Based on these sample results, no further remedial activities were warranted for SWMU 10. An NFA and Covenant Not to Sue was issued by the NJDEP on October 24, 2002 for SWMU 10; therefore, no additional work is proposed for SWMU 10. This SWMU was not retained as needing further evaluation.

5.3.2 SWMU 38 (Clean Water Injection Well J05-W01E)

The site has several clean water injection wells that historically were used for injecting potable water into the deep aquifer unit for storage during times of drought. One of these wells, J05-W01E, is located in the southern area of SWMU 45-1. This well was not used for waste disposal. Based on a downhole video survey, the wells are in good structural condition. In a letter dated March 25, 1993, EPA agreed that NFA is required. Therefore, no further investigation is needed in this area.

5.3.3 SWMU 41-5 (Drum Storage Area)

This SWMU is a drum storage area that was used to store raw materials, finished products, and waste materials associated with manufacturing processes. The area is approximately 3.5 acres and was sampled as part of the Phase I RFI. Investigation results for soil indicated that all metal concentrations with applicable criteria were below the NRDCSCC. No volatile or semi-volatile constituents were detected. This area is currently paved and is used for parking trucks. An NFA and Covenant Not to Sue was issued by the NJDEP for SWMU 41-5 on October 24, 2002; therefore, no additional work is proposed for SWMU 41-5. This SWMU was not retained as needing further evaluation.

5.3.4 SWMU 17 and SWMU 56A

Sections of SWMU 17 are located within the White Products FA. Details about this SWMU are presented in Section 4.3.1. The sections of SWMU 17 (Process Water Ditch System) within this FA were remediated in the early 1990s and replaced with pipes that are currently used to convey stormwater and non-contact cooling water.

5.4 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the White Products FA, a number of areas were identified for further evaluation. This conclusion was based on the historical area review, aerial photograph evaluation, review of existing data from various media, review of historical investigations, and review of existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The chemical process database was queried for the buildings that exist or existed in this focus area and is provided in Appendix D.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this focus area are provided in the tables in Appendix D. Sampling locations and associated chlorobenzene (mg/kg) are shown in Figure 5-4. Figure 5-5 shows chlorobenzene concentrations vs. NJDEP IGW criteria.
- Sediment Data: Sediment is not present in this focus area.
- Surface-Water Data: Surface water is not present in this focus area.
- Groundwater Data: Groundwater analytical data for this focus area are provided in the tables in Appendix D for VOCs, SVOCs, pesticides, herbicides, metals, and TICs for the active B Aquifer wells. Appendix D also provides data tables for the abandoned wells formerly located within the White Products FA. Active and abandoned well locations are shown in Figure 5-6. A total of 15 samples were evaluated: 12 sets from J05-M02B, one set from I05-M01B (installed December 2005), and two sets from J07-M01B.

  In compliance with the NJPDES-DGW Permit No. NJ0083429, groundwater quality in site perimeter wells is monitored. The wells in this program in proximity to this focus area are shown in Figure 5-6. Monitoring well J05-M02B is monitored as part of the DGW program.

  The shallow groundwater flow (see Figure 5-6) in the White Products FA is likely split due to the presence of the Salem Canal to the south. A small portion of the shallow groundwater flow may flow south toward Salem Canal during conditions when the canal water level is lower than the surrounding B Aquifer (gaining conditions), and away from the canal when the canal water level is higher than the surrounding B Aquifer (losing conditions). The remainder of groundwater flows under the area to the northeast and toward the IWS pumping wells.

A primary manufacturing component at the site was chlorobenzene, and this compound was most commonly detected in the soil and groundwater samples. Therefore, chlorobenzene is used to illustrate the contaminant distribution. Analytical data for all constituents in soil and groundwater were reviewed along with chlorobenzene and are presented in Appendix D.

5.4.1 Ponsol #2 Building (770): Western Side of Building Loading Area and Interior Building Trench

The Ponsol #2 Building trench is considered a potential area of interest based on process and waste disposal knowledge. Many chemicals used in the production of Ponsol dyes were solvents (e.g., anthraquinone, chlorobenzene, aniline), and these solvents were used extensively in this building. The waste disposal practices in the early years involved washing wastes into the building trench and out to the ditches that ran to the basins.

The western side of the Ponsol #2 area was associated with storage, loading, and unloading of materials for use in the Ponsol #2 Building. Additionally, a process water ditch ran north-south in this area and connected to the building trenches. No soil samples have been collected in this area. In shallow groundwater from monitoring well J07-M01B (just to the north of the building and near the associated trench and ditch features), compounds of interest including chlorobenzene, carbon tetrachloride, 1,2,4-trichlorobenzene, and aniline have been detected above GWIIA.

5.4.2 Borneol House Trenches and Drainage

The Borneol House (Building 148) trenches and drainage are considered a potential area of interest based on the lack of process and waste disposal knowledge. Process wastewater containing turpentine and other raw materials entered process waste ditches and may have discharged to the Salem Canal prior to 1932. Process wastewater discharged after 1932 was conveyed to the wastewater settling basin at the site interior.

In the shallow groundwater at a nearby well (I05-M01B), compounds of interest have been detected, including ethylbenzene, xylenes, naphthalene, and 1-naphthylamine. The sediment in the Salem Canal has not been sampled at the location of the discharge from the former trench/ditch that passed just north of the former Bornidol House. Additional sampling of Salem Canal sediment is planned for early 2007 as part of the Salem Canal Seep investigation.

5.4.3 White Products North Bulk Storage

The White Products North Bulk Storage area is considered a potential area of interest based on the long use of the area for chemical storage. Releases may have occurred in former storage, loading, and unloading areas to the north of White Products Buildings

149, 152, and 788. Compounds of interest, including 1,1-DCE, 1,2-DCB, cis-1,2-DCE, 4-chloroaniline, and diethyl phthalate, have been detected in shallow groundwater from well I05-M01B (south of former Buildings 149/152).

5.5 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the White Products FA:

- Collect groundwater samples in the vicinity of the North Bulk Storage area to evaluate the potential effects on groundwater quality.
- Collect groundwater samples in the western portion of the Ponsol Colors area because there are currently insufficient analytical data to characterize groundwater quality in this area.
- Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the Ponsol #2 building area to assess groundwater quality and potential presence of DNAPL.
- Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Salem Canal. The sampling will be performed as part of the perimeter investigation.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 5-7.

6.0 FOCUS AREA – DYES

Evaluation of the Dyes FA indicates that further investigation is warranted throughout the FA except in the Administration and Carpentry Shop areas. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

The compounds detected in soil, sediment, and groundwater samples in the Dyes FA are consistent with the chemicals used in the dye processes and at the site in general. In the areas of SWMU 63 and the Salem Canal seep investigation, groundwater samples have elevated SVOC concentration, and DNAPL is present in three wells in the southern portion of the FA.

The FA borders the Salem Canal, and elevated levels of site-related constituents in sediment have been detected in one section of the canal. Additional sediment sampling in the vicinity of former process wastewater outfalls is recommended in order to evaluate the potential impact of legacy discharges.

There are few soil and groundwater sampling locations throughout the Dyes FA. Given the elevated constituent concentrations at those locations where samples were collected, the presence of DNAPL, and the fact that some dyes were produced in multiple areas, it is possible that areas of the former wastewater ditches and building trenches are potential current contaminant sources. Therefore, DuPont recommends collecting groundwater samples in the vicinity of the process wastewater ditches to evaluate groundwater quality and the presence of DNAPL. Additionally, installing monitoring well(s) in the northern portion of the FA is recommended since the spatial extent of characterization of groundwater quality cannot be defined with the current distribution of monitoring wells.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

6.1 Areas of Interest

The Dyes FA encompasses about 39 acres in the south-central portion of the Chambers Works Complex along the Salem Canal. It is bounded by the Triangle FA to the north, the Jackson Laboratory (Jackson Labs) FA to the west, the Salem Canal to the south, and White Products FA to the east (see Figure 6-1).

Ten areas are pertinent to the Dyes FA history, as shown in Figure 6-2. Included are two SWMUs where remedial measures are completed (see *Chambers Works FACT Sheet*, DuPont, 2002):

- ❑ SWMU 41-3: Drum Storage Area
- ❑ SWMU 9: Solvent Recovery Unit 1

A potential pathway analysis was not completed for these areas as part of this PAR. In addition, the Administration area and Carpentry area are not considered for further evaluation in the pathway analysis because these areas have served as non-production areas since dye production began in 1917.

The remaining historical areas are subject to pathway analysis to determine if additional investigations are necessary:

- Sulfuric Acid Plant Area
- Naphthalene Intermediate Area (including SWMU 63: Azo Dye Area)
- Basic Colors and Sulfur Colors Areas (two areas)
- Azo Colors Area
- Ponsol Colors Area

Because the processes were not building specific, the process area was combined into one area for evaluation.

6.2 History

The majority of dye and intermediate compound production, from the beginning of the DuPont company involvement with the dyestuff industry in 1917 until it left the industry in 1980, occurred in the Dyes FA. In fact, this area was responsible for the majority of dye production in the United States, with hundreds of different brand name dyes and an uncountable number of different intermediary compounds being produced. In addition to producing products for market, research and development at the Jackson Labs, and other product-specific laboratories, the Dyes FA also contributed to the development of fluoroproducts (e.g., Freon), tetraethyl lead (TEL), and elastomer products (e.g., "Neoprene" and "Viton"), among others.

This section summarizes the history of the Dyes FA. A more comprehensive history is provided in the in the report titled *Chambers Works History* (DuPont, 1978).

6.2.1 Initial Dye Manufacturing

In the summer of 1915, Dr. A. Chambers was working to develop sources of toluene for DuPont and suggested that DuPont look into the manufacture of a number of dye intermediates, the idea being that these products would be sold to companies already in the dye manufacturing from coal-tar derivatives. In 1916, DuPont purchased from Levinstein Ltd. their completed information on the manufacture of coal-tar dyes and intermediates and embarked DuPont in the dyes business.

Before 1917, the Dyes FA was open land and bordered on a road (Canal Road) to the residential community known as Fenton's Beach. Initial construction of the Deepwater Dyes Works began in 1916-1917. A plant for the production of chlorine and caustic soda by electrolysis of salt was erected southeast of the Deepwater pier (near the center of the TEL FA) and was intended for dual service to the Carneys Point Powder Works and the projected Dye Works operations. Also erected near the Chlorine building was the Sodium Plant and Phenylglycine Building to provide intermediates for the Indigo Factory. In the

Dye FA, other construction projects were started almost simultaneously and included manufacturing facilities for various intermediates and the three main types of dyes (azo, basic, and sulfur colors).

In the spring of 1917, using processes developed at Eastern Laboratory, Gibbstown, New Jersey, some equipment in the picric acid buildings (see Fluoroproducts FA) were adapted to make the first dye at Chambers Works, sulfur black. Sulfur black dye was made from picric acid, dinitrophenol and polysulfide. Four other dyes produced later in 1917 included auramine, indigo, azo, and sulfur colors.

A listing of all of the known buildings is included in Appendix F. Figure 6-2 shows the buildings that were present on the 1939 plant layout map and the 1940 aerial photograph, a year during which much of the dye manufacturing was occurring. Figure 6-2 is a representative depiction of the general layout of the process buildings, storage building, tanks, and other surface structures during the period of active dye manufacturing.

Dyes were produced in batch runs. Therefore, an industrial process string for the production of any particular dye does not exist. Certain dyes or intermediates were primarily made within specific areas. These dyes could also easily have been manufactured in other areas as vacancies or production needs required. It is also possible that multiple dyes were produced at the same place at different times. With the exception of the Sulfuric Acid Plant and the Naphthalene Intermediate area, there is a possibility that any given dye, intermediate compound, or waste stream could have occurred within any process area of the Dyes FA.

The basic building blocks for chemicals and dyes for the Dyes FA can generally be summarized as organic compounds, commonly of benzene derivation. The base products and some of the common building-block chemicals that were used include the following:

- ❑ Base Products
  - Anthracene
  - Benzene
  - Naphthalene
  - Toluene
  - Xylenes
- ❑ Building Blocks (some common intermediates)
  - Alpha & beta-naphthylamine
  - Anthroquinone (reduced anthracene, produced at Chambers Works)
  - Benzidine
  - Chlorobenzene (chlorinated benzene, produced at Chambers Works)
  - Dinitrotoluene
  - Nitrobenzene (nitrated benzene, produced at Chambers Works)
- ❑ Catalysts/Reacting Agents
  - Nitric acid (produced at the Ordnance Works on-site)
  - Sulfuric acid (produced at the Sulfuric Acid Plant on-site)
  - Titanium chloride
- ❑ Select metals

- Antimony
- Arsenic
- Bromine
- Chromium
- Cobalt
- Copper
- Gypsum (a precipitate in some process reactions)
- Lead
- Mercury (catalyzing agent)
- Nickel (catalyst)
- Palladium
- Phosphates
- Platinum
- Sulfates

Vanadium (catalyst in sulfuric acid production)

6.2.2 Sulfuric Acid Plant

The Sulfuric Acid Plant was located within the northwestern portion of the Dyes FA (see Figure 6-2). This area included the Oil of Vitriol Plant (also known as O.V. Plant) and all production buildings, tanks, and support areas used in the production of sulfuric acid, which was widely used throughout the site. The Sulfuric Acid Plant was located south of the Carpentry and Machine Shops (Building 85), west of the Basic Colors Area, east of various storehouses of the Jackson Labs FA, and west and north of the Naphthalene Intermediate area.

Buildings in this area included the O.V. Plant, preheater and converter house, acid storage tank, and a sulfur storage area. A listing of all of the known buildings in this area is included in Appendix F.

The Sulfuric Acid Plant originally consisted of two units with two converters in series and vessels for distilling oleum using platinized asbestos as a catalyst. By 1930, this catalyst was changed to platinized magnesium sulfate. In 1945, the new Leonard Monsanto Plant began operation and used vanadium pentoxide as a catalyst. In 1946, the original units were shut down and later dismantled. The Leonard Monsanto Plant continued operation until the 1980s when it was shut down and eventually dismantled in 1998.

Sulfuric acid was an intermediate chemical supplied to various dye production areas of the site. In addition to sulfuric acid for dye operations, the Sulfuric Acid Plant also produced oleum for the DuPont Carneys Point Works to support nitrocellulose production. Based on inventory records, over 4.5 billion pounds of sulfuric acid were produced at the site from 1917 to 1958. Production is reported to have peaked at 140 million pounds per year in 1941. After 1960, the reduction in dye production at the site and decreasing nitrocellulose production at Carneys Point Works resulted in decreasing demand for sulfuric acid.

6.2.3 Naphthalene Intermediate Area

The Naphthalene Intermediate area was located south of the Sulfuric Acid Plant (see Figure 6-2). At least 27 buildings were located within this area. A listing of all of the known buildings in this area is included in Appendix F. Buildings and tanks within this area were used for the production of naphthalene and other nitrobenzene intermediate compounds that were common building blocks for dye production.

This area was primarily used to create the various intermediate compounds used throughout the site and the Dyes and White Products FAs in particular. Although complete inventory records are not available, a record search provided an indication of the diverse and complex compounds created in this area. As such, no single process history or waste stream data are available.

Because of the nature of intermediary compound batch production, record-keeping during the operational period of this area, and the large number of distinct compounds created, comprehensive production lists are not available. However, records indicate that in the years spanning the 1930s, the Naphthalene Intermediate Area produced about 6.5 million pounds of products annually. This production peaked during World War II at about 32 million pounds annually. In 1958 production was down to about 13 million pounds annually and continued to decline throughout the 1960s and 1970s until all dye-related production ended when DuPont left the dye business in 1980.

6.2.4 Basic Colors and Sulfur Colors Areas

The Basic Colors and Sulfur Colors areas were located in the northwest and south central portions of the Dyes FA (see Figure 6-2). Many building names are associated with the type of dye produced at some time, such as the “Victoria Green Building,” the “Magenta Building,” and the “Sulfur Blue Building.” However, because some processes were relocated over time, it is likely that multiple types of dyes were produced in any given building, regardless of that building’s name. Thus, the processes and chemicals used in this area are more appropriately characterized by examining the collective data, which is representative of the Basic Colors and Sulfur Colors areas as a whole.

Based on a historical records review, the amount of dyes produced per year in this area often was reported generically. However, in 1920, 16 basic colors were produced, and the recorded production was about 1 million pounds annually.

Basic dyes are typically amino derivatives (and acetic acid and softening agents) that are used mainly for application to paper. Sulfur or sulfide dyes contain sulfur or are precipitated from a sodium sulfide bath. Unlike other areas that were largely based around a particular dye process, this area was widely used to run up processes for new dyes created at Jackson Labs and other laboratories. The rate at which the Basics Color Area brought dyes to market implies that this area could have hosted many different compounds (Wingate, 1982).

According to a site retiree, dinitrophenol, a solid organic compound, was produced in the Sulfur Black Building (Building 724) located in the north-central area of the Dye FA (see Figure 6-3). As the chemical was produced, it would granulize and smaller granules would be caught in the updraft through the roof flue, from which it would settle to the surrounding ground. The retiree had no knowledge of any activities to remove any settled material.

6.2.5 Azo Colors Area

The Azo Colors area is located in the eastern central portion of the Dyes FA (see Figure 6-2). At least ten buildings were located within this area. A listing of all of the known buildings in this area is included in Appendix F. The buildings included offices and laboratories, storage, change house, grinding and mixing, and other buildings.

Azoic dyes contain the azo (nitrogen) group and formic acid, caustic soda, metallic compounds, and sodium nitrate. These dyes were made especially for application to cotton and represent the largest quantities, in terms of pounds produced, of all dyes.

A complete discussion of the synthesis of azo dyes could fill several volumes of text. However, at its core, the creation of azo dyes involves the creation of a diazo salt and a coupling component. An example of a diazo salt is diazotized sulfanilic acid that is created through the hydrogenation and nitration of sulfanilic acid. An example of such a coupling is with diazotized sulfanilic acid and 1-naphthylamine. This reaction creates the acidic color 2-Naphthol Orange and the basic color 1-Naphthylamine Red.

Based on a records review, the amount of total dyes produced during the 1940s and 1950s was between 7 to 10 million pounds annually. These production numbers include Azo, Basic Colors, and Sulfur Black.

6.2.6 Ponsol Colors Number 1 Area

The Ponsol Colors #1 Area is located in the eastern central portion of the Dyes FA (see Figure 6-2). Ponsol #1 (Building 179) and the Ponsol Laboratory and Offices (Building 584) are located on the central-eastern portion of the Dyes FA (see Appendix F). Buildings of unknown use and designation are located immediately east of the Ponsol Building No. 1 and likely were used in the production of Ponsol dyes in some manner. At least five buildings were located within this area. A listing of all of the known buildings in this area is included in Appendix F.

In 1918, anthracene color (blue, black, yellow) production began at the site. These dyes eventually fell under the Ponsol Colors trade name. These dyes, also called vat dyes, were impregnated into fiber under reducing conditions within a vat of solutions and then reoxidized to an insoluble form. Natively, these dyes are very insoluble compounds and are some of the highest-quality (and most chemically complex) dyes ever produced.

Historically, the Ponsol # 1 building was used as a potash recovery facility. This facility became obsolete in 1925 when anthroquinone manufacturing ceased at the site. A records review indicated that the building was used for the manufacture of beta-amine intermediates and dyes as well as dye standards for the Sulfur Colors Area. In 1956, the operations were moved to Ponsol # 2 building and the next year the building was dismantled. A history of the Ponsol #2 Building is included in the White Products FA discussion (see Section 5).

6.2.7 Current Conditions

Buildings and processes within the Dyes FA have been progressively dismantled since 1980, when DuPont left the Dye manufacturing business. Figure 6-2 shows the buildings that currently occupy the Dye area. The only operating process buildings within the Dyes FA are the Ethylene Oxide and the White Products "D" building. The remaining buildings are used for storage, maintenance, change houses, or administrative offices and will not be discussed further herein.

Ethylene Oxide Center (115)

Ethylene Oxide (EtO) is purchased by DuPont from an off-site vendor and used in this area to conduct ethyloxylations. This process is used to purify chemical intermediates in support of the Performance Chemicals manufacturing. Wastewater generated during this process is pumped to the on-site WWTP.

White Products “D” Building (888)

The White Products "D" building (888) is currently part of the White Products manufacturing area and produces textile products and surfactants. Waste material from this process is sent to the wastewater treatment plant for disposal. Additional information on the White Products manufacturing process is discussed in Section 5.0.

6.3 Previous Investigations

The SWMUs identified as part of the RFI within the Dyes Focus Area include the following (see Figure 6-2). More complete descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheet* (DuPont, 2002).

6.3.1 SWMU 41-3

SWMU 41-3 was identified by the EPA during a 1987 site analysis as a drum storage area that was used to store raw materials, finished products, and waste material associated with manufacturing processes at the Chambers Works manufacturing area. This area operated prior to 1970, and it is unknown when storage ceased. SWMU 41-3 is a 0.53-acre asphalt paved area. It is currently used as a parking area and as the site of a storage building which covers the majority of this SWMU location. The location of SWMU 41-3 is shown in Figure 6-2. As part of the Phase III RFI, no further action was proposed for SWMU 41-3 because all detected soil concentrations were below NRDCSCC and IGW. This SWMU was not retained as needing further evaluation.

6.3.2 SWMU 9

SWMU 9 was an isopropyl alcohol recovery unit associated with dye manufacturing that was used from 1917 though 1948. The alcohol recovery building was demolished in 1986. The area is now a concrete pad that is used for drummed material storage. The location of SWMU 9 is shown in Figure 6-2. In 2002, a deed restriction was recorded with Salem County. An NFA and Covenant Not to Sue was issued by the NJDEP for SWMU 9; therefore, no additional work is proposed for SWMU 9. This SWMU was not retained as needing further evaluation.

6.3.3 SWMU 63

The objective of the Phase IV RFI investigation for SWMU 63 was to obtain initial characterization data for the SWMU. Results of the groundwater evaluation indicated that SWMU 63 should be considered a high priority SWMU, and removal of DNAL from G06-M03B was recommended by installation of a properly designed recovery well. A new recovery well was installed at the base of the B Aquifer (top of the B/C confining unit) in September 2005 as part of the DNAPL program (G06-M03B). Since subsequent DNAPL surveys in the new recovery well did not detect the presence of DNAPL. DuPont recommended to continue the delineation efforts in the area.

The extent of DNAPL in SWMU 63 has been delineated to the north and south as part of the Salem Canal seep delineation work. However, further delineation in the vicinity of well G06-M03B, and the eastern and western portions of SWMU 63 were deemed necessary.

The work plan (December 21, 2005) was developed using the results and recommendations from the Phase IV RFI report (April 2005). The SWMU 63 investigation is currently ongoing as part of the Phase IV RFI Supplemental Investigation Work Plan. The work plan includes further soil and groundwater investigation in order to better characterize the area for prioritization purposes.

SWMU 63 was retained during the evaluation.

6.3.4 Salem Canal Seep Investigation

In August 2002, during drought conditions, a purple colored seep was discovered entering the Salem Canal from the site. The NJDEP hotline was notified as was the NJDEP case manager. DuPont installed an emergency boom/silt curtain around the area of observed surface water discoloration, approximately 100 feet in length to contain the seep.

In 2002, investigative activities were initiated, including sampling and analysis of surface water and groundwater in the area of the seep to chemically characterize the seep and to evaluate groundwater containment. Because the canal is used for the plant’s fire, process, and potable water supply, the potable water intake was sampled to confirm that contamination was not present. Sampling of Munson Dam potable water intake occurs on a regular basis and current results continue to be below method detection limits. Constituents detected in the seep were primarily organic compounds.

A more extensive surface-water and sediment sampling event was conducted in 2004 to delineate the extent of contamination in sediment. Constituents detected in the sediment exceed screening criteria, but there were no constituents in surface water above ecological criteria inside or outside the silt curtain/boom in November 2004.

In order to determine the source of the contamination, DuPont developed a conceptual model for the seep area. Potential seep source areas were evaluated by reviewing historical aerial photographs, and conducting interviews with former employees. Groundwater sampling conducted in 2003 and 2004 also helped confirm the area of impacted groundwater. The likely source of the contamination was determined to be related to the former Azo dye manufacturing area (now SWMU 63). Azo dye manufacturing occurred in the area from approximately 1918 until 1980. A report summarizing the investigation of the Salem Canal seep area through 2005 was completed and submitted to the NJDEP in June 2005 (Salem Canal Interim Remedial Measure Selection Report).

Based on recommendations in the ISM report, a Pre-Design Investigation work plan was developed in November 2005. Fieldwork for the hydrogeologic and geologic portions of the investigation were completed from December 2005. Currently, groundwater modeling for the area is being completed to better evaluate potential remedial design options. Sediment sampling for delineation purposes is currently ongoing.

The Salem Canal seep area was retained during the pathway evaluation.

6.3.5 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the Dyes FA. Details about these SWMUs are presented in Section 4.3.1.

6.4 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the Dyes FA, some areas were identified for further evaluation. This conclusion was based on the historical area review, aerial photograph evaluation, review of existing data from various media, review of historical investigations, and review of existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❑ Chemical Process Database: The chemical database does not contain any relevant data for the Dyes FA. Since no chemical processes have ever been done in the Administration Building, this building was not retained for evaluation.
- ❑ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- ❑ Soil Data: Soil analytical data for this focus area is provided in Appendix D. Boring locations and chlorobenzene concentrations are shown in Figures 6-4 and 6-5.
- ❑ Sediment Data: Sediment analytical data for this focus area are provided in Appendix D. Sediment sample locations and chlorobenzene concentrations are shown in Figure 6-6. Sediment data for this focus area are related to SWMU 41-3 as well as the Salem Canal Study area.
- ❑ Surface-Water Data: Surface-water analytical data for this focus area are provided in Appendix D. Sample locations and chlorobenzene concentrations are shown in

Figure 6-7. Surface-water data for this focus area are related to the Salem Canal Study area. These samples are discussed in more detail below.

- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. Chlorobenzene concentrations in B Aquifer wells are shown in Figure 6-8. In general, groundwater flows towards the east-northeast towards IWS pumping well. In the vicinity of the canal, groundwater flow direction is either towards or away from the canal depending on seasonal conditions.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements as noted above. A primary manufacturing component in the Dyes FA was chlorobenzene, and this compound was most commonly detected in the soil, sediment, and groundwater samples. Therefore, chlorobenzene is used to illustrate the contaminant distribution.

In addition, the Administration area and Carpentry area are not considered for further evaluation in the pathway analysis because these areas have served as non-production areas since dye production began in 1917. For evaluation of the Dyes FA, all process areas were combined as an area of interest due to limited available analytical and historic process data.

6.4.1 All Process Areas

As discussed throughout the pathway analysis evaluation, the following process areas within the Dyes FA warrant a pathway analysis:

- Sulfuric Acid Plant Area
- Naphthalene Intermediate Area (including SWMU 63)
- Basic Colors and Sulfur Colors Areas (two areas)
- Azo Colors Area
- Ponsol Colors Area

These areas have been combined into one unit for the pathway evaluation because they share a common production history using similar compounds, production methods, and disposal practices.

In general, review of the compounds detected in soil, sediment, and groundwater are consistent with the chemicals used with the Dyes Area and within the site in general. In the area of SWMU 63 and the Salem Canal seep investigation area, constituent concentrations in soil and groundwater are above applicable criteria, and DNAPL is present in three wells.

As shown in the figures, there are few soil and groundwater sample locations throughout the Dyes FA. Given the high constituent concentrations and presence of DNAPL and the network of former process wastewater ditches, other source areas may be present in this focus area. Therefore, additional sampling is recommended.

6.5 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Dyes FA:

- ❑ Collect groundwater samples in the Basic Colors area because there are currently insufficient analytical data to characterize groundwater quality in this area.
- ❑ Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the Sulfuric Acid Plant area, Basic Colors-Sulphur Colors area, Naphthalene Intermediate area, and Azo Colors area to assess groundwater quality and potential presence of DNAPL.
- ❑ Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Salem Canal. The sampling will be performed as part of the perimeter investigation.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 6-9.

7.0 FOCUS AREA – JACKSON LABS

Assessment of the Jackson Labs FA indicates that further investigation is warranted throughout the FA except in the Power and Utilities (P&U) area. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

Monitoring wells along the perimeter of the FA along the Delaware River indicate elevated levels of site-related constituents. These detections may be the result of historical discharges in the vicinity of Buildings 1205, J-26, Former Building 36 (Indigo Factory), and Building J-24, where most of the process wastewater ditches were present. Therefore, collection of groundwater samples is recommended to evaluate groundwater quality and the presence of NAPL and DNAPL in order to assess these features as potential sources of groundwater contamination. Similar sampling is recommended in the vicinity of an outfall sump.

DuPont recommends additional groundwater sampling along the site perimeter in the southwest portion of the FA where there are limited analytical data to evaluate groundwater quality and the potential for groundwater to surface-water pathways. In addition, installation of additional wells may be needed in order to enable calculation of horizontal hydraulic gradient and therefore assess hydraulic containment by the IWS.

The Jackson Labs FA borders the Delaware River and Salem Canal. Therefore, sediment sampling in the vicinity of former process wastewater outfalls is recommended in order to evaluate the potential impact of legacy discharges.

The rail unloading area adjacent to process buildings in the Indigo area may have had historical releases. Therefore, DuPont recommends additional groundwater sampling downgradient of the primary Indigo unloading areas to enhance spatial coverage and to evaluate groundwater quality for the presence of site-related constituents.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as the number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

7.1 Areas of Interest

The Jackson Labs FA is approximately 32 acres in the southwest corner of the site (see Figure 7-1). It is bounded by the Salem Canal to the south, the Delaware River to the west, Fire Road to the north, and Main Street to the east.

Based on common processes, history, chemical use, and disposal practices, the Jackson Labs FA has been divided into four sub areas (see Figure 7-1):

- The Laboratories area is in the southwestern portion of the focus area where laboratories and support buildings were located for chemical process research and development.

- The Semi-Works area is in the northwestern portion of the focus area where pilot-scale chemical production occurred. This area currently produces chemical intermediates for the elastomers business at the site.
- The Power and Utilities area is in the southeastern portion of the focus area where the powerhouse and water treatment plant are located.
- The Former Indigo Heavy Chemicals area is in the northwestern portion of the focus area where the Indigo Dye manufacturing operation was located.

As shown in Figure 7-2, several SWMUs are located within the Jackson Labs FA and have been investigated and/or remediated as part of the Chambers Works RFI program. These SWMUs are covered in Section 7.2 but do not require additional evaluation as part of the pathway analysis since no new information was identified that requires additional investigation:

- SWMU 28: Telomer "A" Waste Container Storage
- SWMU 29: Telomer "A" Waste Treatment Tank
- SWMU 33: Manhattan Project-Related Area
- SWMU 31: Fly Ash Disposal Area
- SWMU 51: Well DW-8
- SWMUs 41-6 and 41-7: Drum Storage Areas 6 and 7

More complete descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

Based on the aerial photograph review and process knowledge, several areas of interest were selected for further evaluation:

- Former Outfalls Associated with SWMU 17
- SWMU 39-5 [Former Underground Storage Tank (UST) and Aboveground Storage Tank (AST) location]
- Main Switching Station and Transformer Pad area
- Rail Unloading Spots in Former Indigo Heavy Chemicals and Naphthalene areas

The areas of interest are shown on Figure 7-3.

7.2 History

Before 1917, the location of the Jackson Labs FA was a residential community known as Fenton's Beach, consisting of 62 individual lots and associated streets. In 1917, DuPont began to purchase the individual lots and consolidate them into a single property for the Deepwater Dye Works. The property acquisition continued until the final lot was purchased in 1927.

Initial construction of the Deepwater Dye Works began in 1917 with the construction of the Jackson Laboratory and the Technical Laboratory for research and development activities. The Power and Utilities buildings (powerhouse, boiler house, substation, icehouse, and filter plant) were constructed to supply electricity, steam, potable water, ice, and compressed air to the Dye Works. DuPont also constructed the Indigo Heavy Chemicals buildings and associated railroad spurs directly north of the Power and Utilities area to manufacture synthetic indigo dyes. In 1918, DuPont began the Semi-Works operation by installing equipment in the former Fenton's Beach schoolhouse. Initially, Semi-Works activities included process development and pilot-scale production of dye formulations developed by the Jackson Labs research and development (R&D) department. Additional construction continued from 1918 to 1927 as the remaining residential properties were acquired and replaced with buildings associated with the Deepwater Dye Works.

Current operations in this FA are discussed below by areas within the FA.

7.2.1 Laboratories Area

The Laboratories area includes 12 primary buildings used for laboratory research and development and office space, and approximately 30 support buildings used for storage shops (carpenter, machine, glassware, etc), and the Chambers Works plant fire house. Research and development activities in the Jackson Labs FA have continued without interruption from 1917 to the present. Initially, R&D activities were focused on the dye business but grew rapidly to support other products, including petroleum additives, synthetic rubber (Neoprene), Freon, plasticizers, Teflon®, Nomex, and Kevlar. Product formulations and manufacturing processes were developed in the laboratories and later pilot-tested in the Semi-Works area if the development showed promise. Many product formulations and processes evaluated in the laboratories did not progress to the pilot test stage. Historical records indicate that nearly every chemical that was ever used or produced in any operating area of the Chambers Works was tested in the laboratories at some point (DuPont, 1978). Process waste from the buildings in the laboratory area was historically conveyed to the adjacent process waste ditch and is currently collected in waste sumps and pumped via overhead pipeline to the on-site WWTP.

There are no SWMUs located within the Laboratories Area other than sections of SWMU 17 (see Section 4.3.1).

7.2.2 Semi-Works Area

The Semi-Works area currently contains three process buildings (J-26, 1205, and 207), an office building, and several storage buildings/sheds currently associated with the DuPont Performance Products division (see Figure 7-2). Pilot testing has been conducted in these buildings, and several previously demolished buildings, to troubleshoot the manufacturing process prior to large-scale production in other areas of the site. The pilot-scale test runs required several months to several years depending on the product line. At the conclusion of pilot-scale testing, the process building was retrofitted with the equipment needed for the next set of tests. Product formulations and processes yielding successful test runs were relocated to other operating areas of the Chambers Works for large-scale production if there was a market for large quantities of the product. In many cases, the Semi-Works operations generated quantities sufficient to meet market demand and, for that reason, continued producing products for an extended period of time. Over time, significant quantities were manufactured in the Semi-Works area. For example, in the 18-year period between 1940 and 1958, over 3,000 pilot-scale test runs were conducted and over 85 million pounds of products were produced (DuPont, 1978). These products included finished products that were shipped to off-site customers, or intermediate products that were supplied to other operating areas of the Chambers Works.

Current operations in the Semi-Works area include specialty monomer production in support of the elastomers product line. These operations are part of the Performance Chemicals West (PC West) area and include Buildings 1205, 1207, J-25, and J-26. The three specialty monomers are C_4/C_6 mixed perfluoro-dido alkanes (PDA-4,6), idodetrafluoro-1butene (ITFB or Monomer 4431), and bromotetrafluoro-1-butene (BTFB). These monomers are used by the DuPont Performance Elastomers operation to make Viton synthetic rubber.

SWMU 28 (Telomer "A" Waste Container Storage Area)

SWMU 28 is a concrete loading bay attached to Building 1050 that is completely enclosed and elevated approximately 3 feet above grade. The storage area floor consists of concrete that is sloped to a drain that leads to the WWTP. Concrete or asphalt covers the area outside of the porch for 50 feet in all directions. The waste that was stored at SWMU 28 was a highly corrosive sludge that generated hydrofluoric acid upon exposure to water or moist air. Wipe sampling conducted during closure of the storage area did not detect Telomer A waste residue (iodide and fluoride). The RCRA-regulated unit was certified as partially closed by NJDEP in a letter dated November 18, 1986. As part of the Phase III RFI, a soil and groundwater sample were collected and analyzed for SWMU related constituents (iodide and fluoride). Groundwater sampling results indicated the presence of fluoride and iodide in groundwater, but no regulatory criteria were available for comparison. The RCRA Unit Post Closure Monitoring Program began for this SWMU in July 2003 in accordance with the NJPDES-DGW permit No. NJ0083429. A downgradient well (C08-M01B) is monitored annually for SWMU-related constituents (iodide, fluoride, and antimony) and reported in the NJPDES-DGW Semiannual Status Report.

SWMU 29 (Telomer "A" Waste Treatment Tank T-130)

SWMU 29 is the Telomer "A" catalyst residue and filter bag treatment facility waste treatment tank T-130. This unit was closed in accordance with the DuPont closure plan dated July 26, 1990 and the NJDEP Hazardous Waste Facility Permit dated June 17, 1998. Closure of this unit was documented in the *NJ Licensed Professional Engineers Certification of Closure Report Telomer "A" Catalyst Residue and Filter Bag Treatment Facility, DuPont Chambers Works, Deepwater NJ* dated April 30, 2001.

SWMU 33 (Manhattan Project-Related Area)

Six areas are identified as SWMU 33 at the site. These areas are currently being investigated by the USCOE as part of the Formerly Utilized Sites Remedial Action Program (FUSRAP) project. A portion of SWMU 33 (see Figure 7-2) is located in the Jackson Labs FA within the footprint of Building J-26. In 2006, the USCOE conducted groundwater and soil sampling around Building J-26 to screen for the presence of uranium related to former Manhattan Project activities. The final investigation report is expected to be available in early 2007. During the FUSRAP investigation, the presence of NAPL was reported in the A fill zone to the northeast of Building J-26. DuPont installed an A zone well (D08-M01A) in late 2005 to screen for the presence of the observed NAPL. Monthly NAPL screening has been conducted during 2006 and NAPL has not been detected. Results of the NAPL screening program are reported in the NJPDES-DGW Semi-Annual Status Reports.

7.2.3 Power and Utilities Area

The Power and Utilities area contains two primary operating buildings and several supporting structures. These buildings (powerhouse, boiler house, substation, icehouse, and filter plant) were constructed to supply electricity, steam, potable water, ice, and compressed air to the Dye Works in 1917. Water was initially obtained from supply wells located on-site, but the amount of water wasn't sufficient to meet plant needs. In 1933, DuPont constructed Munson Dam across the Salem Canal at the site (and Brown's Dam several miles upstream) to isolate the freshwater Salem Creek from the brackish water in the Delaware River, creating a freshwater reservoir. A freshwater intake was constructed at Munson Dam, and a water filtration system was constructed south of the Boiler House. The boilers were initially designed to burn coal, but later were converted to use oil prior to 1939. By 1957, the energy needs of Chambers Works exceeded the existing capacity, and DuPont began to obtain steam and electricity from the Atlantic Electric Deepwater generating station located south of the Salem Canal. Between 1959 and 1962, the fuel oil storage tanks were removed and replaced with a new water treatment plant. DuPont has been supplied with steam and electricity from the Carneys Point Cogeneration Facility since the early 1990s. Current operations in the Power and Utilities area include distribution of steam and potable water to the site in addition to producing and distributing compressed air. The water treatment plant operates in compliance with both federal and state Safe Drinking Water Act requirements. Monitoring results are reported to the NJDEP Bureau of Safe Drinking Water under program ID PWSID No. NJ1708300.

SWMU 31 (Power Plant Coal Pile and Fly Ash Disposal Area)

SWMU 31 consisted of the former coal pile for the Chambers Works powerhouse and fly ash resulting from the powerhouse operation. Coal was fed to the powerhouse boilers to produce steam for the plant. This practice ended in the 1950s when electric generation ceased and the powerhouse was used to provide compressed air for the plant. The area is now paved with asphalt.

As part of the Phase III RFI, a soil and groundwater sample were collected and analyzed for TCL organics plus 10 and TAL metals. Soil results did not indicate SWMU-related constituents above NRDCSCC. Groundwater results indicated concentrations of some metals and polynuclear aromatic hydrocarbons (PAHs) above criteria. The elevated metals results were thought to be elevated due to the turbidity of the sample resulting from the sampling method (DuPont, 2002). Groundwater in the area is captured by the IWS and no additional investigation was proposed for SWMU 31.

SWMU 51 (Well DW-8)

Production well DW-8 (E07-W01F) was equipped with an oil-lubricated pump from approximately 1943 to 1962. The pump was replaced with a water-lubricated pump in

1962. The water-lubricated pump was removed in April 1989 due to the presence of oil in the well. The source of the oil was determined to be the lubricating oil from the pump. In a letter dated July 25, 1995, the EPA and NJDEP agreed that DW-8 was thoroughly investigated and required no further action.

7.2.4 Former Indigo Heavy Chemicals Area

The Indigo Heavy Chemicals area was constructed in 1917 and operated continually until DuPont ceased production in the early 1970s. Primary buildings in the area included the Indigo Factory (Building 36), Indigo Storage & Shipping (Building 603), Indigo Melt (Building 33), Caustic Melt (Building 43), as well as shops, storage sheds, and an office. The primary product in this area was a synthetic indigo dye. This dye was first produced by reacting chloroacetic acid, aniline, ferrous sulfate, and caustic soda to form iron glycine. Iron glycine was treated with caustic soda and caustic potash to form phenylglycine, the primary intermediate for indigo dye. The initial process included several washing and filtration steps that reduced efficiency. In 1920, an improved glycine process based on formaldehyde and sodium cyanide was adopted, improving efficiency. In the 40-year period from 1919 to 1959, approximately 260 million pounds of indigo paste and powder were produced. Process wastewater from the manufacturing process was conveyed into the PWDS (SWMU 17; see Section 4.3.1) located along the western edge of the operating area. A rail yard located to the east of the operating area was used for loading/unloading of raw materials and finished product. This rail yard was shared by both the Indigo Heavy Chemicals area and the Naphthalene Intermediates area to the east. The operating buildings associated with the indigo dye production were removed prior to 1974 with the exception of Building 603, which is currently used as office space.

SWMUs 41-6 and 41-7 (Drum Storage Areas)

SWMUs 41-6 and 41-7 are drum storage areas within the Former Indigo Heavy Chemicals Area (0.47 acres and 0.64 acres, respectively) that were used to store raw materials, finished products, and waste material associated with manufacturing processes at the site. Currently, both SWMUs are covered with gravel. These SWMUs were investigated as part of the Phase I RFI. Results indicated that all VOCs, SVOCs, and metals concentrations were below NRDCSCC. An NFA and Covenant Not to Sue were issued by the NJDEP for SWMUs 41-6 and 41-7 on October 24, 2002.

7.2.5 SWMU 17

Sections of SWMU 17 ditches are located within the Jackson Labs FA. Details about SWMU 17 are presented in Section 4.3.1.

7.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the Jackson Labs FA, areas were identified for further evaluation. This conclusion is based on review of historical area information, aerial photographs, existing data from various media, previous investigations, and existing remedial documentation. This section provides the information that was collected and discusses the evaluation.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The chemical process database was queried for the buildings that exist or existed in this focus area. Historical process research indicates that solid waste material was usually removed from the area and transported to other areas of the site for incineration or landfill disposal. Liquid waste was drummed for incineration and or landfill disposal, or discharged to the PWDS.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this focus area are provided in Appendix D. Sampling locations are shown in Figures 7-4 and 7-5, with soil results posted for chlorobenzene compared to NRDCSCC and IGW, respectively.
- Sediment Data: No sediment analytical data for this focus area were available.
- Surface Water Data: No surface water analytical data for this focus area were available.
- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D for VOCs, SVOCs, pesticides, herbicides, metals, and TICs for the active and abandoned B Aquifer wells.

  Grab groundwater data collected from temporary well-points for this focus area are provided in Appendix D.

  In compliance with the NJPDES-DGW Permit No. NJ0083429, groundwater quality in site perimeter wells is monitored. The wells in proximity to this focus area that are monitored as part of the DGW program (F06-M02B, D06-M01B, C07-M01B, and C08-M01B) are shown in Figure 7-6.

  The shallow groundwater flow (see Figure 7-6) in the Jackson Labs FA is tidally influenced by the Delaware River to the west. Groundwater in the B Aquifer in the western portion of this FA flows toward the river while the eastern portion flows to the east toward the IWS pumping wells.

The general suite of SVOCs present at many areas at the site has also been detected in soil and groundwater in the Jackson Labs FA. PCE was present at elevated concentrations at most locations and therefore is used to illustrate the contaminant distribution. Analytical data for all constituents in soil and groundwater were reviewed in addition to PCE.

7.3.1 Former Outfalls Associated with SWMU 17

Several historical outfalls were located in the Jackson Labs FA that may have discharged process wastewater to the Delaware River.

Sediment samples will be proposed in the perimeter investigation work plan to characterize the sediment in the river for site-specific constituents. This work plan will be submitted after agency review and approval of the PAR.

The process waste sump associated with former permitted outfall 010 has been historically used as a collection point for process wastewater in the area. It is located at the site boundary in and area where B aquifer discharges to the Delaware River and may have historically released site constituents to the B Aquifer. Therefore, groundwater sampling at this location is recommended to evaluate groundwater quality and potential groundwater to surface-water pathways.

7.3.2 SWMU 39-5 (Former UST and AST location)

SWMU 39-5 was the location of a former UST adjacent to Building 1128 (Water Treatment Plant) and two aboveground oil storage tanks from 1917 to 1960. For the aboveground tanks, secondary containment berms were present. The UST was removed, and soil was checked for visual evidence of contamination and odor after UST removal; no evidence of leakage was observed. In a letter dated December 6, 1993, the EPA agreed that SWMU 39-5 required no further action.

SWMU 39-5 is near the southern perimeter of the Power and Utilities Area where groundwater containment in the B Aquifer is uncertain. In addition, groundwater data in the area are limited. Transformers and switching stations are also present in this area. Therefore, DuPont recommends additional investigation in this area to evaluate groundwater quality and potential groundwater to surface-water pathways.

7.3.3 Rail Unloading Spots in Former Indigo and Naphthalene Areas

Rail unloading spots adjacent to process buildings that have been in continual operation have the potential for historical releases to soil and groundwater. Groundwater data and soil data in the area are limited; therefore, the potential for historical releases to the environment is unknown.

DuPont proposes investigation of groundwater adjacent to the primary Indigo and Naphthalene unloading spots to enhance spatial coverage in the area and to evaluate groundwater quality for the presence of site-related constituents.

7.3.4 Groundwater Evaluation

Evaluation of PCE in soil and shallow groundwater was chosen for evaluation for the Jackson Labs FA because it was commonly used material in the area and was also detected in soil and groundwater in this area. Soil concentrations of PCE are posted in Figure 7-4 and 7-5, and groundwater concentrations are shown in Figure 7-6. An evaluation of available groundwater quality data indicates detections of site constituents above criteria. A lack of spatial coverage for groundwater prevents adequate delineation of the extent of the current groundwater impact in this FA.

Process sumps and ditches associated with operating Buildings have the potential for historical releases to the environment. Several buildings were identified in consideration of the operational history, waste disposal practices, and review of available groundwater quality data as having an increased potential for historical releases for additional evaluation. These buildings include the following:

- J-26 (Jackson Labs Product Development Laboratory)
- 1205 (Performance Products West Miscellaneous Products)
- Former Building 36 (Indigo Factory)
- J-24 (Pharmaceutical Chemicals R&D)

DuPont proposes additional investigation to access the potential releases from process sumps and ditches adjacent to these buildings to evaluate groundwater quality for the presence of site-related constituents.

7.4 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Jackson Labs FA:

- Collect groundwater samples along the site perimeter in the southwestern portion of the Labs area, including the sump location of the former outfall, to evaluate groundwater quality and potential groundwater to surface-water pathways.
- Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the area of buildings J-24, J-26, 36, and 1205 to assess groundwater quality and potential presence of DNAPL.
- Collect groundwater samples downgradient of the former Indigo and Naphthalene loading/unloading area to evaluate the potential effects on groundwater quality.
- Measure hydraulic head in aquifer at multiple locations near the FA perimeter to calculate horizontal hydraulic gradient and therefore assess hydraulic containment by the IWS.
- Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Delaware River. The sampling will be performed as part of the perimeter investigation.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 7-7.

8.0 FOCUS AREA – TEL

Assessment of the TEL FA indicates that further investigation is warranted throughout the FA. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

The TEL area was used to produce anti-knock fuel additives, mainly tetraethyl lead (TEL). Tetramethyl lead (TML), trimethylethyl lead (TMEL), and sodium-lead alloy were also produced, so the primary manufacturing component in the TEL FA was lead. Accordingly, lead has been detected at elevated levels in soil throughout much of this FA. Concentrations of total lead in groundwater in the western portion of the FA exceed applicable criteria. Insufficient groundwater analytical data exist to define the groundwater concentration throughout the FA. Therefore, additional groundwater sampling is recommended to characterize groundwater quality downgradient of and in the former manufacturing area.

Groundwater flow is predominantly toward the east as a result of the IWS. However, based on the water levels in the current monitoring wells, which are mostly along the site perimeter, there appears to be a groundwater divide such that shallow groundwater may be flowing towards the Delaware River. Measurement of hydraulic head at additional locations is therefore recommended to enable calculation of the horizontal hydraulic gradient and therefore confirm hydraulic containment by the IWS.

Currently, there are no monitoring wells on the eastern portion of the FA. Collection of groundwater samples downgradient of the former TEL area, associated ditch system, and ethyl chloride AST farm and railroad loading/unloading area is recommended in order define the spatial distribution of site-related constituents in groundwater and to evaluate whether these areas are sources of groundwater contamination.

The TEL FA is bordered by the Delaware River. Therefore, sediment sampling in the vicinity of former process wastewater outfalls is recommended in order to evaluate the potential impact of legacy discharges.

The full evaluation is presented in the rest of this section. Details regarding the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

8.1 Areas of Interest

The TEL FA encompasses approximately 38.5 acres along the eastern bank of the Delaware River. The TEL FA is bounded by the Delaware River to the west; the Fluoroproducts FA to the north; Jackson Labs FA to the south; and the Aramids, Triangle, and Dyes FAs to the east (see Figure 8-1).

A number of areas are pertinent to the TEL FA history, as shown in Figure 8-2. These include the following four SWMUs where investigations/remedial measures have been completed and do not warrant any further discussion in the pathway analysis section:

- SWMU 25: Lead Flue Dust and Lead Furnace Slag Storage Area
- SWMU 39-2: Underground Storage Tank
- SWMU 40: Fuel Oil Storage Tanks
- SWMU 41-8: Drum Storage Area

A pathway analysis of the Antiknocks area (SWMU 57) was conducted to determine if additional investigation is necessary. This area includes SWMU 6 (Landfill II), C Ditch Process Water Ditch System, TEL process and storage buildings, ethyl chloride AST farm, and railroad loading/unloading areas.

In Figure 8-3, the areas of interest are labeled. More complete descriptions of SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

8.2 History

Tetraalkyllead compounds (including TEL) were marketed for use as gasoline motor fuel additives (leaded gasoline), which suppress engine “knock” and hence were called “anti-knocking” agents.

The original process involved lead sodium alloy containing 17.2% sodium, which was made in 2,900 pound lots by melting lead and sodium in a steel kettle and casting into large pans with loose covers. The alloy was then allowed to cool and solidify and was ground under a blanket of CO_2 and discharged into milk cans. Sodium bromide was then reacted with ethyl chloride in a medium of sulfuric acid and distillation of the reaction mass.

The first location of TEL production was in the idle Saltpeter Refinery Building (left over from Carneys Point and WWI), which was remodeled, and equipment was installed for producing ethyl bromide, lead disodium, and TEL. Plant production of TEL started in August 1923. In August 1924, TEL production reached a rate of 1.2 million pounds per year. In 1924, a new plant (called “A”) was being built for ethyl chloride process of TEL, which did not require the use of bromine. Ethyl chloride was not manufactured in the TEL area. However, it was used in the process of TEL production and was stored in several storage tanks in the focus area as shown in Figure 8-2.

In 1925, DuPont separated the TEL area into its own distinct operation area. Ethyl chloride was purchased from other firms from 1924 until 1927, when the Basic Color area was assigned to manufacture ethyl chloride for TEL. Additional ethyl chloride facilities were installed at the site in 1937 and 1943; however, DuPont still purchased it from other firms (Dow, Shell, and National Distillers).

In 1929, the second TEL building plant “B” started production. In 1930, the third plant “C” started production. A fourth building “D” was built in 1930 and by 1935 a fifth building, plant “E”, was in operation. Additionally in 1935, ethyl chloride bulk storage and recalcification equipment was moved to a remote location. Production increased during WWII to meet demand for use in both auto and plane fuel. Due to increases in demand, DuPont worked on accelerating the reaction rates and developed a process that used acetone as a catalyst. By 1957, the production for the Antiknocks area was 194 million pounds per year.

The EPA began to regulate the lead content of domestic gasoline starting in approximately 1973. This resulted in a gradual decline in the production of TEL at the site, which ultimately led to the business shutdown in 1991 and decontamination and demolition of the site structures between 1991 and 2001. Approximately 300,000 pounds per day of TEL was produced in the last few production years.

Aqueous streams from the TEL area were combined with water run-off from the production area and pumped to an accelerator clarifier for lead recovery. The clarifier required pH adjustment with hydrochloric acid (HCl) due to the high pH of the wastewater. The adjustment facilities precipitated inorganic lead salts, which were dewatered with a centrifuge. Solids recovered in the centrifuge were directed to a spray furnace for lead recovery.

The clarifier overflow was discharged into the “C” Settling Basin (SWMU 16; see Section 12) to which sodium borohydride was added. The overflow from the basin was directed to the plant wastewater treatment facility while the dredged solids were centrifuged.

Additional process information is provided in Appendix H. Groundwater and soil data associated with the TEL area are further discussed in the pathway analysis section.

8.2.1 SWMU 25: Lead Flue Dust and Lead Furnace Slag Storage Area

SWMU 25 was an asphalt storage area used exclusively for the storage of lead wastes produced at the Thermal Decontamination Furnace (SWMU 21) and lead treatment areas (see Figure 8-2). Waste were stored here and later shipped off-site for disposal. Because lead flue dust was designated as a hazardous waste under RCRA, SWMU 25 is regulated under RCRA.

During a site inspection conducted by representatives of the NJDEP Bureau of Planning and Assessment, cracks in the asphalt pavement were observed. A sampling program was developed to analyze for total lead to determine the extent of contamination. Asphalt sample results were elevated for lead, so the asphalt surface was washed and resampled. Lead concentrations in the asphalt samples remained elevated. Lead concentrations in groundwater samples were also elevated. In 1991, remedial actions conducted by DuPont included the excavation of the asphalt pad, placing a layer of geotextile over the area exposed by the removal of asphalt and placing crushed stone over the area. The underlying soil was to be addressed as part of SWMU 57. SWMU 25 has been certified closed by the NJDEP. The RCRA Unit Post Closure Monitoring Program began for this SWMU in July 2003 in accordance with the NJPDES-DGW permit No. NJ0083429. A downgradient well is monitored annually for SWMU-related constituents and reported in the NJPDES-DGW Semiannual Status Report. The groundwater in this SWMU is monitored as part of the perimeter monitoring plan. No further work is being proposed in this area.

8.2.2 SWMU 39-2: Underground Storage Tank

SWMU 39-2 is part of a network of 19 former USTs that were located at the site (see Figure 8-2). These tanks contained gasoline, diesel, or waste by-products. The tanks have been removed; no visual evidence of leakage was observed during removal. Based on these results, the EPA agreed to no further action for SWMU 39 and no further work is proposed as a result of this evaluation.

8.2.3 SWMU 40: Fuel Oil Storage Tanks

SWMU 40 comprises three fuel oil storage tanks (TS-1, TS-2, and TS-3) as shown in Figure 8-2. TS-1 and TS-2 were constructed in the 1930s, and TS-3 was constructed in the 1970s. The tanks were once used to store No. 6 fuel oil, but have been emptied and are currently not in use. SWMU 40 is surrounded by an asphalt and gravel covered berm, and each tank is spill controlled by an asphalt-covered dike containment structure. Soil samples collected from within and around SWMU 40 did not indicate the presence of fuel oil. Piezometers in the area have not indicated the presence of free product. DuPont recommended no further action in the Phase II RFI for SWMU 40; and, based on this review, no further work is proposed.

8.2.4 SWMU 41-8: Drum Storage Area

SWMU 41-8 is a former drum storage area, which had been used to store raw material, finished products, and waste material associated with manufacturing operation at the site (see Figure 8-2). SWMU 41-8 was sampled as part of the Phase II RFI and data indicate benzo(a)pyrene concentrations slightly exceeded NRDCSCC. Additional sampling indicated benzo(a)pyrene concentrations were below the NRDCSCC and that the area has been delineated. Currently, the SWMU is covered with concrete and is no longer active. DuPont recommended no further action in the Phase II RFI for SWMU 41-8; and, based on this review, no further work is proposed.

8.2.5 Antiknocks Area

The Antiknocks area (SWMU 57) is a 25-acre section of the TEL FA located along the eastern bank of the Delaware River (see Figure 8-1). This area was used in the production of MFAC using tetraethyl lead and related compounds from 1923 until 1991. In addition to TEL, the Antiknocks area was used to produce tetramethyllead (TML), tetramethyl-ethyl lead (TMEL), and sodium-lead alloy.

Seventeen buildings (648, 648A, 1249, 647, 1121, 1258, 1170, 765, 856, 1032, 618, 653, 731, 536, 661, 568, and 563) were associated with the production and storage of TEL and similar products. The majority of buildings in the TEL FA have been dismantled and only some building foundations remain. The only current operating unit in the area is the SET organic stripper. This unit receives off-site waste with high organic content and uses a steam stripper to separate the wastewater from the organic non-aqueous phase liquid. The wastewater is conveyed to the WWTP for treatment, and the non-aqueous liquid is drummed and shipped off-site for disposal. Operation of the organic stripper is performed in accordance with SET procedures and applicable permits.

8.2.6 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the TEL FA. Details about these SWMUs are presented in Section 4.3.1.

8.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1.

Based on the historical assessments presented above, the Antiknocks area (SWMU 57) is subject to pathway analysis to determine if additional investigation is necessary. This area includes SWMU 6 (Landfill II), C Ditch Process Water Ditch System, TEL process and storage buildings, ethyl chloride AST farm, and railroad loading/unloading area.

This conclusion was based on review of the historical area information, aerial photographs, existing data from various media, previous investigations, and existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The TEL area was used to produce tetrethyl lead, an anti-knock preventative agent for automobiles. Additionally, TML, TMEL, and sodium-lead alloy were produced in the Antiknocks area. The raw materials, intermediates, products and wastes were reviewed as part of this evaluation.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this focus area are provided in Appendix D. Boring locations are shown in Figure 8-4. Further discussion of relevant data is discussed in the following section.
- Sediment Data: Sediment samples were not collected in the TEL focus area.
- Surface-Water Data: Surface-water samples were not collected in the TEL focus area.
- Groundwater Data: Groundwater data are available for nine active wells located along the eastern perimeter of the focus area. These nine wells have been sampled periodically over time, and a few of the wells are sampled as part of the perimeter monitoring program that is reported in the semi-annual DGW reports. Well locations, total lead concentrations, and groundwater flow are shown in Figure 8-5. Groundwater flow is predominantly to the east, as a result of the IWS; however, a groundwater divide exists near to the boundary with the Delaware River, and shallow groundwater could discharge to the Delaware River.

The primary manufacturing component in the TEL FA was lead, and this compound was most commonly detected in the soil and groundwater samples. Therefore, total lead is used to illustrate the contaminant distribution.

8.3.1 SWMU 57, SWMU 6, C Ditch PWDS, and TEL Process/Storage Buildings

SWMU 57 is the Antiknocks Area, which also includes all historical TEL process and storage buildings. SWMU 6 (Landfill II) is also located within SWMU 57 and is included as part of the discussion for SWMU 57.

Characterization sampling of SWMU 57 and SWMU 6 indicated the primary constituents of concern are inorganic and organic lead compounds. The highest concentrations of lead were found in the subsoil of C Ditch. Elevated lead concentrations have been detected in the areas of both SWMU 57 and SWMU 6. SPLP lead concentrations are also elevated and indicate a potential source of lead in groundwater.

Much of SWMU 57 is covered by building foundations, asphalt, concrete, or crushed stone, thereby minimizing potential exposure to soil. Two areas in the northern portion of the SWMU were either not covered or were covered with fill material. Soil samples were collected in these areas during Phase III RFI, and lead and TEL were detected in the samples above criteria. Air sampling of these areas also was conducted to evaluate potential exposure to workers in the area. Results indicated lead and TEL below detection limits for air sampling. Lead samples were generally collected from shallow depths. DuPont recommended inspection and maintenance of the gravel cover over this area to reduce exposure potential.

The C Ditch PWDS, which consisted of 2,000 feet of open and partially uncovered ditch, was used to carry wastewater generated during the production of motor fuel antiknock compound (MFAC) in the Antiknocks area. The ditch system is present in Figure 8-2. The wastewater was discharged from the ditch into a sump and pumped to the Antiknocks lead pretreatment facility. Process waters contained various lead compounds. Solids from the process waters in the Antiknocks area settled out and accumulated in the ditches. The solids that settled there were remediated from the ditch between 1989 and 1991. Wastewater was pumped to the Antiknocks area lead pretreatment facility for pH adjustment and solids removal. All sludge was removed from the ditch system and also processed through the lead pretreatment facility.

Sampling conducted along the ditch system was conducted to delineate and/or characterize the bottom soils in the ditch. Soil samples were collected from within the boundary of the ditch system and analyzed for total lead and lead compounds including TEL. Soils data indicated concentrations of total lead, TEL, and low concentrations of VOCs. Additional sampling was conducted in the ditch system for analysis of total lead, total organic lead, and select VOCs (chlorobenzene and 1,2-dichlorobenzene). Several samples exceeded the screening level for lead. Total organic lead was also detected in several samples, but VOC concentrations were below screening levels. Shallow ditch samples generally demonstrated the most significant concentrations of lead and total organic lead. It was determined that total lead and total organic lead should be the only analytes for further sampling within the Antiknocks Area.

Based on the results of the Antiknocks area PWDS sampling, DuPont and the NJDEP agreed to excavate all soil beneath the C Ditch that exceeded 10,000 ppm total lead. At the request of NJDEP, pre-excavation samples were collected every 250 linear feet along the ditch. Sampling was conducted to define the vertical extent of total lead concentrations to a depth of 20 feet below grade. Several samples exceeded the screening level for total lead and the results were used to define the limitations of the excavation of the ditch.

Remedial actions completed for the C Ditch system, included the following:

- ❑ Performed in-situ stabilization of 41,800 cubic feet of subsoil contained within the C Ditch with total lead concentrations of greater than 10,000 ppm.
- ❑ Excavated and placed the treated subsoil into the vault located within the boundaries of the A/B Basin hazardous waste management unit.
- ❑ Installed a storm conveyance system to maintain plant drainage.

It was recommended after the initial ditch sampling event, that no further characterization sampling of the PWDS be required because the ditch has been characterized to the groundwater table and concentrations in sidewall samples are similar to those found in the remainder of SWMU 57. Closure has not been obtained for the C Ditch system.

Lead concentrations exceeding NRDCSCC were detected in several soil samples collected in and along the ditches and in areas of former building foundations (see Figure 8-4).

Lead concentrations in groundwater for this FA are shown in Figure 8-5. As shown in the figure, there are insufficient data across most of the FA to define groundwater quality. Collection of groundwater samples downgradient of the former TEL manufacturing area and associated ditch system is recommended to evaluate whether these areas are potential sources of groundwater contamination.

8.3.2 Ethyl Chloride AST Farm and Railroad Loading/Unloading Area

No groundwater data have been collected for the ethyl chloride AST farm (Buildings 661 and 771; Figure 8-4) and the adjacent railroad loading/unloading area that is located in the northern portion of the FA. Therefore, collection of groundwater samples downgradient of these features is recommended to whether these areas are potential sources of groundwater contamination.

8.4 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the TEL FA:

- ❑ Collect groundwater samples downgradient of the process wastewater ditches and process building trenches in the eastern side of the FA because there are currently insufficient analytical data to evaluate groundwater quality downgradient of these potential sources.
- ❑ Collect groundwater samples in the vicinity of the AST farm to evaluate the potential effects on groundwater quality.

- ❑ Collect groundwater samples in the FA interior because there are currently insufficient analytical data to characterize groundwater quality in this area.
- ❑ Collect groundwater samples downgradient of the former railroad loading/unloading area to evaluate the potential effects on groundwater quality.
- ❑ Measure hydraulic head in aquifer at multiple locations near the FA perimeter to calculate horizontal hydraulic gradient and therefore assess hydraulic containment by the IWS.
- ❑ Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Delaware River. The sampling will be performed as part of the perimeter investigation.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 8-6.

9.0 FOCUS AREA – FLUOROPRODUCTS

Assessment of the Fluoroproducts FA indicates that further investigation is warranted throughout the FA. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

Fluoroproducts such as Freon® were produced in the Kinetic area, and elevated concentrations of compounds typical of raw products and waste stream products, such as trichlorofluormethane, dichlorodifluoromethane, chloroform, carbon tetrachloride, and PCE, are present in monitoring wells. Elevated concentration of these compounds are present in a shallow well that is close to a former trench segment and former outfall, suggesting the ditches may be former or current sources to groundwater. Unlike other areas of the Chamber Works manufacturing area, some of the process wastewater ditches in the Fluoroproducts FA were not remediated. Therefore, these ditches may be sources for groundwater contamination. Collection of groundwater samples is recommended in the vicinity of ditch segments to evaluate groundwater quality and the presence of NAPL and DNAPL. Installation of a monitoring well in the vicinity of the former outfall is also recommended to evaluate the potential for groundwater to surface-water pathways.

Additional monitoring well(s) are recommended for areas downgradient of the ditch network because there is currently an insufficient number of wells to characterize the spatial extent of contaminated groundwater.

Collection of groundwater samples is also recommended in the former petroleum tank area and alcohol area because there are currently no analytical data to characterize groundwater quality.

The Fluoroproducts FA borders the Delaware River. Therefore, sediment sampling in the vicinity of former process wastewater outfalls is recommended in order to evaluate the potential impact of legacy discharges.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

9.1 Areas of Interest

The Fluoroproducts FA is approximately 52 acres and located in the northwest section of the Chambers Works manufacturing area (see Figure 9-1). This focus area is bounded by the Delaware River to the west, the Basins FA to the north-northeast, and the TEL FA to the southwest and includes Kinetic and Freon Roads.

Based on common processes, history, chemical use, and disposal practices, the Fluoroproducts FA has been subdivided into the following two distinct areas: the former Alcohol Plant and former Kinetic area (see Figure 9-1).

A number of areas or features are pertinent to the Fluoroproducts FA history, as shown in Figure 9-2. These include six SWMUs where significant investigative and/or remedial measures are completed, so there is no need for a potential pathway analysis as part of this PAR. The nine investigated/remediated SWMUs are as follows:

- SWMU 5A: Landfill I
- SWMU 20: Ethyl Chloride Incinerator
- SWMU 26: Freon Spent Catalyst Storage Area
- SWMU 33: Manhattan Project Area
- SWMU 34: Gypsum Disposal Area
- SWMU 35: Freon Disposal Impoundment
- SWMU 39-3: USTs
- SWMU 55-4: Fill Deposition Area
- SWMU 59: Disposal Area V

A summary of previous investigations for these SWMUs is discussed in Section 9.3. These SWMUs have been previously investigated and an evaluation of available data indicates that further evaluation of these areas is not required in the pathway analysis.

Several additional historical features are present within the Alcohol Plant and Kinetic area that are considered areas of interest (Figure 9-3).

9.2 History

The Fluoroproducts FA includes Plant 4, which was established by the DuPont Explosive Department to manufacture picric acid. The first picric acid was produced in 1915 by nitration of phenol and production of dimethylaniline (DMA) for conversion to tetryl. Plant 4 became known as the “High Explosive Plant.” The plant was built in the Deepwater Point area, mainly due to the natural fire barriers, proximity to Carneys Point Works (and its transportation and process water supply structures), and room for expansion.

In 1915, two still houses located near the riverfront were installed to extract benzene, toluene, naphtha, and other hydrocarbons from coal-tar. Production of benzene, toluene, xylene, naphthalene, solvent naphtha was increased in 1916 with the addition of a cracking plant. The picric acid manufacturing was augmented in 1917 by a supplementary process and equipment to make ammonium picrate, which was used in American military explosives. Sulfur black dye was also manufactured in the High Explosive Area when the Dye Works first began dye development.

In 1915, the Saltpeter Plant was built near the waterfront about midway between the Explosive Plant and Salem Canal mouth. The plant refined crude nitrate by removing impurities and providing high quality sodium nitrate to the powder plants.

9.2.1 Former Alcohol Plant

The Alcohol Plant was located on the southern side of the Fluoroproducts FA. In the early 1900s, the plant also included storage areas and the sodium sulfide house. The Eastern Alcohol Corporation was formed in 1925 and was jointly owned by DuPont and Kentucky Alcohol Co. (subsidiary of National Distilleries Corporation).

Construction of the Alcohol Plant began in 1925 and operations started a year later. Production during the first five months of operations was nearly 3 million gallons of alcohol. The basic process for manufacturing alcohol was to pump, via pipelines, molasses transported by ship to large storage tanks. The molasses would then be diluted and "cooked" as partial pasteurization. It was then fermented with yeast cultures to produce beer. From beer, the alcohol was distilled. The initial plant included the following buildings: fermenter house, still house, denaturing house, bonded warehouse, drumming building, maintenance shop, change house, office, and six steel tanks each capable of holding over 1 million gallons of molasses.

The by-product of carbon dioxide gas was purchased by Solid Carbonic Co. for making dry ice starting in 1927. Under a land-lease agreement with DuPont, the Solid Carbonic Co. built a plant adjacent to the Alcohol Fermentation building.

In 1931, a new building for the production of butyl alcohol, acetone, and isopropyl alcohol by fermentation was completed. The process was discontinued in 1932. In 1933, the Alcohol Plant started to produce its own antifreeze compound consisting of a blend of alcohol and rust inhibitors called the "Five-Star Anti Freeze". Distribution of the anti-freeze was discontinued in 1948. Alcohol production during WWII ranged from 25.5 to 26.6 million gallons per year.

In 1953, fermentation was discontinued. The following year, one-third of the former Alcohol Plant was leased to Pure Carbonic Division of Air Reduction Corporation, which generated carbon dioxide gas from petroleum combustion.

Based on the 1917 plant layout map, one toluol tank storage area and a series of oil tanks were present in the area near SWMU 33.

9.2.2 Former Kinetic Area

The former Kinetic area is located on the northern side of the Fluoroproducts FA. The former Kinetic area was used for nitrating and sulfur black production as well as Freon production. In 1930, Kinetic Chemicals, Inc., was formed and jointly owned by DuPont and GM for the purpose of manufacturing Freon to be used as refrigerant. Freon research began immediately in 1930 at Jackson Labs at the Dye Works Plant until a continuous process was developed. At least six different Freon refrigerants were manufactured in the Fluoroproducts FA, including Freon-11, Freon-12, Freon-113, Freon-114, Freon-22 (raw product in "Teflon"), and Freon-21.

The basic chemical reaction involves bringing organic material together with hydrofluoric acid (HF) in the presence of a catalyst (i.e., antimony chlorofluoride. Common organics used in the basic chemical reaction include the following:

- ❑ Carbon tetrachloride (CCl_4; F-11 and F-12)

- Chloroform ($CHCl_3$; F-21 and F-22)
- Tetrachloroethene (PCE) a.k.a. perchloroethylene (F-113 and F-114)

The first plant built for Freon manufacturing was the Freon Building (K-1) and was located in the northern portion of the focus area. By October 1931, a second manufacturing unit was installed to meet demand. A hydrofluoric acid (HF) plant was built to supply the raw material necessary for Freon production. Other major process changes or historical significant events included the following:

- By late 1932, other Freon products were being manufactured, including "Freon-113" and "Freon-114" with a small amount of "Freon-11" being produced.
- From 1934 to 1935, PCE was substituted for hexachlorethane as the starting material for Freon-114.
- In 1936, the process was changed to improve Freon drying by substituting alumnia gel for the sulfuric acid tower process.
- By 1941, "Freon-21 and "Freon-22" were added to the Kinetic product list.
- In 1942, HCl by-product was recovered (it was previously discharged with trade waste to the ditches).
- In 1944, new plants for "Freon-12" and HF were completed, doubling the capacity of the area.
- During WWII, the demand for Freon increased sharply. A third manufacturing unit was erected in a new building beside the first two units. In the 1950s, Kinetic Chemicals was acquired entirely by DuPont.
- In about 1953, DuPont started to ship Freon in pressurized tank cars and trucks. In conjunction with new shipping procedures, nine 10,000 bulk storage tanks were erected.
- In 1955, DuPont stopped manufacturing zinc silicofluoride and "Freon-22" at the site.
- In 1956, DuPont celebrated the billionth pound of Freon products being produced.
- In 1957, the organization name was changed from the Kinetic area to the Freon area.

A second ethyl chloride plant (Plant 2) was constructed in approximately 1937 and was located adjacent to the Kinetic plant on the site of the old High Explosive Plant buildings. This plant recovered hydrochloric acid that was formerly discharged to the process waste ditch as a waste product from the Freon production in the Kinetic area. Approximately 0.5 million pounds of HCl were condensed from coolers.

Ethyl chloride was made by the aluminum chloride-catalyzed reaction of anhydrous hydrogen chloride (HCl) with ethylene. Waste from this process consisted of waste gas (containing HCl, ethyelene, and ethyl chloride) and liquid waste (contained HCl, aluminum chloride, ethylene chloride, and high boiling organic impurities).

A by-product of the process was 50,000 to 95,000 pounds of salt cake. Most of the salt cake (>60%) was sold. All ethyl chloride production was suspended in 1945 and resumed in 1949. By 1955, all of the ethyl chloride production at the site was being made in the "Kinetic" area.

Various tanks were observed starting in the 1939 plant layout map in the eastern section of the Kinetic area near the site perimeter. The original tanks were for the ethyl chloride operations and the buildings associated with the tanks indicated that nitrating was being completed in this area. Later, more Kinetic buildings and associated tank areas were built in this area. Another tank handling area was present in the northwest corner of the Kinetic area.

9.2.3 Current Operations

Freon production ceased in the early 1980s. Current production in this focus area involves three classes of chemicals: propellants, electronic gases, and refrigerants. Current operations include the manufacturing of three products: HFC-125, HFC-227ea and PFC-116. The compounds HFC-125 and HFC-227ea are produced in the same building, K-39 (FE™ Products), and PFC-116 is produced in Building K-40 (Zyron® Products). Additional products HFC-23, Zyron® 8020, and HFC-236 are purified or transloaded in the area. DuPont Fluoroproducts also produces the following classes of chemicals:

- Electronic gases (Zyron® 116, Zyron® 23, and Zyron® 8020)
- Refrigerants SUVA® 95 and Freon 23
- Fire Extinguishants FE-36™, FE-13™, and FE-227™

The area continues to use hydrofluoric (HF) acid as a basic building block (raw material) in chemical processes. Wastewater is discharged into collection tanks and pumped to the WWTP via overhead pipeline.

9.3 Previous Investigations

The SWMUs identified as part of the RFI within the Fluoroproducts FA include the following:

- SWMU 5A: Landfill I (see Section 12 for details about the SWMU 5 previous investigation)
- SWMU 20: Ethyl Chloride Incinerator
- SWMU 26: Freon Spent Catalyst Storage Area
- SWMU 33: Manhattan Project Area
- SWMU 34: Gypsum Disposal Area
- SWMU 35: Freon Disposal Impoundment
- SWMU 39-3: USTs
- SWMU 55-4: Fill Deposition Area

- SWMU 59: Disposal Area V

More complete descriptions of these SWMUs were previously submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

9.3.1 SWMU 20 (Ethyl Chloride Incinerator)

SWMU 20 is 2.4 acres and is located in the northern portion of this focus area (see Figure 9-2). The two-unit, ethyl chloride incinerator was used to burn waste products associated with ethyl chloride operation. The incinerator had two water scrubbers in series that prevented particulate release to the air. In addition, 12 emergency interlocks prevented accidental releases. This unit began operation in 1971, operated under interim status in Building 1126, and was monitored under RCRA Part B and NJDEP Air Permit #PC42570/65076/076. The only waste stream that entered SWMU 20 was comprised of ethyl chloride, ethylene, aluminum chloride, hydrochloric acid, and various hydrocarbons The year that operations ceased is unknown. Currently, SWMU 20 is considered clean closed under RCRA according to EPA correspondence. Based on this determination, no further investigation of this SWMU is necessary.

9.3.2 SWMU 26 (Freon Spent Catalyst Storage Area)

SWMU 26 is a storage area that contained a 6,000-gallon lined railroad tank car that was used until 1942 to store spent antimony pentachloride. SWMU 26 is located in the former Kinetic area along Ethyl Chloride Street. DuPont submitted a RCRA closure plan for SWMU 26 in 1984 and investigated this SWMU as part of the Phase III RFI. Closure certification reports were approved by NJDEP, and a postclosure groundwater monitoring program is in effect. The RCRA Unit Post Closure Monitoring Program began for this SWMU in July 2003 in accordance with the NJPDES-DGW permit No. NJ0083429. A downgradient well (G14-M01B) is monitored annually for SWMU-related constituents and reported in the NJPDES-DGW Semiannual Status Report.

9.3.3 SWMU 33 (Manhattan Project Area)

SWMU 33 is located in the southeastern portion of the Fluoroproducts FA and in the northern part of the General Stores area of the Aramids FA (see Figure 9-2). This SWMU is an area that was used by the Manhattan Engineering District (MED) and the Atomic Energy Commission (AEC) from the 1940s through 1960s for radiological activities. SWMU 33 is being investigated as part of the Department of Energy (DOE) FUSRAP program (created to address remaining radiological contamination). The two areas under investigation are located in the Fluoroproducts FA – Former Building 845 Area (including the wooden trough and ditch section that borders the northeast and east portion of this area) and the F Parking Corral (the site of former Building 708). Several radiological surveys, as well as a remediation of B Ditch (SWMU 56A), have been completed for this area.

Beginning in 1942, DuPont entered into an agreement with the U.S. Army Corps of Engineers (AOCE) to conduct manufacturing operations at two locations: the Blue Products area and the East area. The East area is discussed as part of the Miscellaneous

FA (see Section 19). The Blue Products Area was located adjacent to the Alcohol Plant at the southeast border. Beginning in April 1943, the Blue Products operations occupied an idle building known as the Glycerine Building (formerly used by the Alcohol Plant) while four small operating buildings in the area were completed. Production activities in the Blue Products area continued until February 1945. By June 1947, operations in the Blue Products Area had ended, and most of the buildings in the area were rapidly dismantled. By February 1948, dismantlement was complete.

A report was prepared describing the ACOE FUSRAP activities (Roy F. Weston, 2003). Key conclusions from the report are as follows:

- Building 845: Exposure from the residual radiological contamination in the building was substantially below the DOE protection guideline of 100 mrems/year – maximum exposure for DuPont employees was 9 mrem/year, and residual radioactive material remaining in the building did not pose a potential threat of future exposure.
- Parking Lot F: Low-level uranium contamination was detected in the soil.

The ACOE removed nine drums of mixed waste and approximately 40 bags of PPE in 1998. (The PPE was the result of DOE investigation efforts.) In 1999, DuPont completed building demolition. The ACOE investigation of this SWMU is ongoing, and reports describing these investigations are currently being developed by ACOE.

9.3.4 SWMU 34 (Gypsum Disposal Area)

SWMU 34 is 4.3 acres and is located in the western portion of the focus area (see Figure 9-2). This SWMU consists of two areas that were used for the disposal of calcium sulfate (gypsum), a by-product associated with the hydrogen fluoride production process. The SWMU operated prior to 1950 (exact date unknown) to 1962 (due to the installation of the ditch system). The two areas in this SWMU were investigated as part of the Phase II RFI.

Key conclusions in the RFI were as follows:

- No further soil sampling was necessary because all soil sample constituent concentrations were below the NRDCSCC.
- Soil in this SWMU could be a source of groundwater contamination for antimony and lead based on a conservative comparison of SPLP concentrations to GWIIA criteria. This comparison does not account for attenuation and dilution.

Monitoring wells immediately downgradient of SWMU 33 can also be samples for these compounds to assess whether these soils are a source of groundwater contamination.

9.3.5 SWMU 35 (Freon Disposal Impoundment)

SWMU 35 is located near the central portion of this focus area in the former Alcohol Plant area (see Figure 9-2). In May 1993, DuPont requested that the area identified as SWMU 35 be removed from the HSWA permit renewal application (submitted May 7, 1993). In a December 6, 1993, letter to DuPont, the EPA requested further documentation (e.g., personnel interviews, historical information) to support the removal request. Information was provided in the Phase I RFI report submitted to the EPA on May 26, 1995.

In the 1988 RFA, the EPA concluded that a surface impoundment once existed in the Fluoroproducts FA. The EPA identified the surface impoundment on a 1940 aerial photograph that is contained in the 1987 EPA Environmental Photographic Interpretation Center study. The SWMU 35 surface impoundment identified by the EPA did not appear on any of the later photographs (1951, 1959, 1965, and 1981), and no earlier photographs exist in the EPIC study to document the existence of the impoundment prior to 1940. However, the impoundment is noted on the 1917 and 1939 building layout maps.

Because DuPont has no records of the presence of a surface impoundment in this area, historical maps of the site from 1917 and 1948 were examined to determine if this impoundment once existed. On the 1917 map, the area identified as SWMU 35 was defined as a reservoir. Directly adjacent to the reservoir was a fire pump, water tank tower, and powerhouse. On the 1948 map, the unit identified as a reservoir was not present.

DuPont interviewed a site retiree who worked at the site from 1933 to 1995 performing various functions. To the best of the retiree’s knowledge, the SWMU 35 surface impoundment was actually a freshwater basin and was not used to hold any type of waste material. Based on this information, no further action is proposed in this area.

9.3.6 SWMU 39-3 (USTs)

SWMU 39 is located in the northwest portion of the Fluoroproducts FA (see Figure 9-2). Only one UST was located in this focus area and it was used to store gasoline and/or diesel products. The UST was removed from the site prior to 1993. Based upon EPA correspondence dated December 6, 1993, no further action was granted for this SWMU.

9.3.7 SWMU 55-4 (Fill Deposition Area)

SWMU 55-4 is 17.3 acres and is located along the eastern portion of this focus area (see Figure 9-2). Based on the aerial photograph review, this SWMU operated prior to 1940. Based on a records review, no records of fill origin exist. The Phase II RFI boring logs indicate that the fill consists of orange-brown, silty sand and gravel with concrete rubble, bricks, and occasional wooden debris .

According to the Phase II RFI, the majority of the soil samples had either no exceedances of the NRDCSCC or had few metals and/or PAH compounds that slightly exceeded the NRDCSCC. There were some noted exceedances of the IGW. However, based upon engineering and institutional controls, no further sampling was recommended.

9.3.8 SWMU 59 (Disposal Area V)

SWMU 59 was identified in 1995 from a reference to a “waste disposal” on the 1917 map of Chambers Works (as seen on the 1917 plant layout map). The area is currently covered by gravel and is located north of the current operating facilities. The area is approximately 1,700 square feet. Results of characterization sampling indicate that lead was the only metal to exceed the NRDCSCC. The other constituents that were detected but did not have applicable criteria included phenanthrene, acenaphthlyene, and benzo(ghi)perylene. Based upon engineering and institutional controls, no further sampling was recommended.

9.3.9 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the Fluoroproducts FA. Details about these SWMUs are presented in Section 4.3.1.

9.4 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1.

For the Fluoroproducts Focus Area, the Alcohol Plant and Kinetic area were identified for further evaluation. This conclusion was based on reviews of historical information, aerial photographs, existing data from various media, previous investigations, and existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❑ Chemical Process Database: The chemical process database was queried for the buildings that exist or existed in this focus area.
- ❑ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- ❑ Soil Data: Soil analytical data for this focus area are provided in Appendix D. Twenty-six soil sample locations and analytical results were available for review. Most of the sampling was completed as part of the RFI process. The main compounds of potential concern in soil included carbon tetrachloride, PCE, nitrobenzene, and chloroform (known breakdown compound of carbon tetrachloride). Sampling locations are shown in Figure 9-4 with soil results posted for carbon tetrachloride compound that exceeded criteria compared to NRDCSCC. Figure 9-5 shows soil results posted for carbon tetrachloride compound compared to IGW.
- ❑ Sediment Data: Sediment analytical data for this focus area were available for the remedial action completed at SWMU 5. Since this area has been remediated, no further discussion of this data is necessary.
- ❑ Surface Water Data: No surface water analytical data for this focus area were available. No further discussion is necessary.
- ❑ Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. Groundwater data were compared to GWIIA.

In compliance with the NJPDES-DGW Permit No. NJ0083429, groundwater quality in site perimeter wells is monitored. The wells in this program in proximity to this focus area (D14-M01B, E15-M01B, E16-M01A, F16-M01B, and G16-M03B) are shown in Figure 9-6. In addition, monitoring wells H14-M01B, G16-M02B and H16-P01B are monitored for the closure and post-closure of the A, B, and C Basins. Data associated with these wells undergo a rigorous statistical evaluation and are submitted to the NJDEP as part of the DGW program in semi-annual reports.

The shallow groundwater in the Fluoroproducts FA is tidally influenced by the Delaware River to the west. The B Aquifer in the western portion of this area may flow toward the river while the eastern portion flows to the east toward the IWS pumping wells. The groundwater flow and impacts in the deeper aquifers is discussed on a site-wide basis in Section 3.5.

Because it was a significant raw material used in the production of Freon, carbon tetrachloride in soil and shallow groundwater is used to illustrate the contaminant distribution. Soil concentrations of carbon tetrachloride are posted in Figures 9-4 and 9-5; shallow groundwater concentrations of carbon tetrachloride are shown in Figure 9-6.

9.4.1 Alcohol Plant

Because the construction and use of the oil tanks described previously is not well understood and because the tanks were present over most of the Alcohol Plant area, further investigation of potential petroleum impacts to groundwater is recommended.

9.4.2 Kinetic Area

The tank handling areas were located in the vicinity of monitoring wells, D15-M01B, E15-M01B, and E16-M01B, so additional sampling locations are not required there. However, one shallow well E15-M01B was found to intersect or be in proximal to a former trench segment and just upgradient of the outfall location. Evaluation of the shallow groundwater data indicates high levels of typical Kinetic/Freon raw products and waste stream products such as: trichlorofluormethane, dichlorodifluoromethane, carbon tetrachloride and PCE exist in the groundwater. This suggests that areas where other former ditch sections are present in the Kinetic area could be contributing to elevated groundwater concentrations. Therefore, collection of groundwater samples in the area is recommended.

9.5 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Fluoroproducts FA:

- Collect groundwater samples downgradient of the process wastewater ditches and process building trenches in the Kinetic area because there are currently insufficient analytical data to evaluate groundwater quality downgradient of these potential sources.

- ❑ Collect groundwater samples in the vicinity of the oil tanks in the Alcohol area to evaluate the potential effects on groundwater quality.
- ❑ Collect groundwater samples along the site perimeter in the northwest potion of the FA to evaluate groundwater quality and potential groundwater to surface-water pathways.
- ❑ Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the Kinetic area to assess groundwater quality and potential presence of DNAPL.
- ❑ Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Delaware River. The sampling will be performed as part of the perimeter investigation.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 9-7.

10.0 FOCUS AREA – ARAMIDS

Preliminary assessment of the Aramids FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

DuPont recommends installing additional B Aquifer monitoring wells in the Elastomers/Isocyanates area adjacent to the former MVA and Hylene Plants to enhance spatial coverage and to evaluate groundwater further. This area warrants additional investigation due to the presence of NAPL in monitoring wells, the lack of available groundwater quality data in the area, and the presence of process wastewater ditches. A monitoring well in the vicinity of the former MVA plant's building trenches and confluence with the B Ditch contained NAPL, including elevated levels of PCE, TCE, cis-1,2-DCE, carbon tetrachloride, toluene, and chlorobenzene. NAPL also was detected in samples from another well northeast of the former Hylene Plant and also within the A Ditch; these samples contained elevated levels of constituents consistent with the compounds (e.g., nitrobenzenes) used and produced in the Naphthalene Intermediates area of the Triangle FA that drained to the A Ditch.

DuPont recommends sampling groundwater in the vicinity of the General Shops/Storage and the Parking Lot/Aramids areas to enhance spatial coverage and to evaluate groundwater further to determine if areas of interest have contributed to elevated concentrations in groundwater. Areas of interest in the General Shops/Storage areas included the former naphthalene plant, the lead melt pot and lead shop, the combined shops wash pit, and the tar still. Reviews of soil and groundwater data indicate little spatial sampling coverage in these areas. Areas of interest in the Parking Lot/Aramids area included the ditch from the Triangle FA to the Basins FA (SWMU 56A), the sand blast and tank areas, the former location of DNT ASTs, and the former pond. Reviews of soil and groundwater data indicate little spatial sampling coverage in these areas. DuPont recommends sampling groundwater in the southern portion of the Parking Lot/Aramids area to increase spatial coverage. Groundwater in the vicinity of the former pond and DNT ASTs should be analyzed for DNT and former raw and production materials from the Acetylene and MVA plants.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

10.1 Areas of Interest

The Aramids Focus Area is approximately 56 acres located in the northwest-central portion of the site (see Figure 10-1). It is bounded by the Triangle FA to the south, the Fluoroproducts and TEL FAs to the west, the Basins and Fluoroproducts FAs to the north, and the SWMU 8 FA to east.

As shown in Figure 10-2, the Aramids FA has been divided into these areas based on common manufacturing and disposal practices, history, and chemical use:

- General Shops/Storage Area: This area includes current and historical location of various shops (welding, blacksmith, paint, engineering, instrument), storage buildings, and offices; no chemical operations were conducted in this area.
- Parking Lot/Aramids Area: This area was the former location of an employee parking lot from 1945 to 1975. The current location of the Aramids manufacturing operation was constructed in 1975.
- Elastomers/Isocyanates Area: This area was the former location of Neoprene (synthetic rubber) production, which was supplanted by isocyanates (Hylene) from 1949 to 1980; currently, this area is part of the Elastomers operations.

The following SWMUs are located in the Aramids FA:

- SWMU 39: USTs
- SWMU 55-3: Fill Deposition Area
- SWMU 55-4: Fill Deposition Area
- SWMU 56: Area of Elevated ODCB in B Ditch
- SWMU 56A: Historic PWDS, including the following:
  - 2,4 DNT section of SWMU 56A
  - Central section of SWMU 56A in FA
  - Section of SWMU 56A along western edge of FA
- SWMU 17: PWDS
- SWMU 38: Clean Water Injection Wells
- SWMU 33: Manhattan Project

In addition, as shown in Figure 10-2 and Table 2-1, remedial investigations and/or interim stabilization measures have been completed at the following SWMUs (see *Chambers Works FACT Sheet*, DuPont, 2002):

- SWMU 39: USTs
- SWMU 55-3: Fill Deposition Area
- SWMU 55-4: Fill Deposition Area
- SWMU 56: Area of Elevated ODCB in B Ditch
- SWMU 56A: Historical PWDS
- SWMU 17: PWDS
- SWMU 38: Clean Water Injection Wells
- SWMU 33: Manhattan Project

These SWMUs are described in the Previous Investigations section of this chapter. Because these SWMUs have been investigated and/or remediated, there is no need for a pathway analysis as part of this PA. In summary, Figure 10-3 shows the areas of interest and SWMUs that were evaluated to determine if a pathway analysis is required.

10.2 History

This section summarizes the history of the Aramids FA in three areas: General Shops/Storage, Elastomers/Isocyanates, and Parking Lot/Aramids. Before 1917, most of the area that would become the Aramids FA was open area or was being used by the Carneys Point Powder Works for storage of nitrocellulose and smokeless gunpowder.

10.2.1 General Shops/Storage Area

Before 1919, this area was used by the Carneys Point Powder Works for storage of nitrocellulose and smokeless gunpowder. During the 1920s, the operating structures associated with the Carneys Point Works were replaced by new structures to support the expanding Deepwater Dye Works. By 1939, there were several shops in the area including blacksmith, welding, tin, lead, pipefitting, paint, and sand blast shops along with various storage buildings, change houses, and offices associated with these shops. Operations in this area were part of the Chambers Works Engineering Department from the late 1920s to the 1990s. The Engineering Department provided services to the entire site, including carpentry, pipefitting and insulation, electrical work and instrumentation, welding, painting, and rail car repair and maintenance. The Engineering Department was restructured in the early 1990s, and most of the associated buildings were demolished by 2000.

Most of this area is currently inactive, but some operations remain including the electrical and instrument shop (Building 1016) and an adjacent change house (Building 776).

10.2.2 Elastomer/Isocyanate Area

In the early 1920s, the DuPont Organic Chemical Department (Orchem) began the manufacturing of Neoprene. Acetylene was made into monovinylacetylene (MVA) and chlorobutadiene (CD) and then was polymerized to an elastomer. This synthetic rubber product from monovinylacetylene and hydrochloric acid was announced under the name “Duprene” in 1931 and was later renamed “Neoprene” in 1936.

A small building was erected to house three component processing operations: MVA, chlorobutadiene, and polymerization. (The MVA unit lies within the Aramids FA.) Additional buildings were constructed for the generation of acetylene from calcium carbide (see Section 11). The final polymer was isolated by drowning in alcohol; eventually the process was converted for use with carbon tetrachloride. By May 1933, the first lot of “Duprene” latex was manufactured in the new plant built between the Triangle and Aramids FAs. The main use for the polymer at the beginning of production was to coat the inner surfaces of drums used at the Dye Works, which protected the quality of the valuable dye pastes and textile specialties.

In 1935, a second plant (Plant B) was constructed to the east of the original plant and produced both MVA and CD. In January 1938, an explosion destroyed this MVA-CD production building; a new building (Plant C) was constructed in 1940. During WWII, “Neoprene” operations ran at full capacity – approximately 24 million pounds per year.

By 1949, all Neoprene production was discontinued at the site. The Plant B finishing building was converted to a new process – polyisocyantes. The rest of the MVA buildings were razed; and, by 1955, construction of a new polyisocyanates manufacturing plant was underway.

Manufacturing of isocyanates at the site dates from around 1937 to 1940. In the 1940s, the first Orchem isocyantates (hexamethylene disocyanate as well as diphenylmethane diisocyanate, or MDI) were made at the Jackson Labs FA. From about 1940 to 1943, the Semi-Works area made small lots of MDI. In 1954, processes were chosen for the manufacture of hydrogen, carbon monoxide, and phosgene and were located at the former Neoprene area (MVA Buildings 757 and 811).

The former Neoprene office and laboratory building became the administrative office. Three of the former Neoprene buildings were adapted for maintenance shops, product loading and warehousing, and product development. Construction began in 1955 and continued into 1956. The trade name “Hylene” was chosen for the organic isocyanates product. Production statistics are not available for the Elastomers business unit, but records indicate that 1957 saw strong growth in the elastomers business. In 1958, a continuous dinitrotoluene (DNT) unit rated at 60 million pounds per year was installed west of the Neoprene area (Building 1140 and storage tanks 1144) to supply DNT to the Hylene plant. By the late 1950s, facilities had the capability to produce 35 million pounds per year of elastomer products.

10.2.3 Parking Lot/Aramids Area with Current Operations

In general, the northeast section of the Aramids FA was a parking lot from the 1940s until the mid-1970s, when portions of the current Aramids operations slowly expanded from the east toward the west.

These compounds are used in Nomex and Kevlar fibers. Current operations in the Parking Lot/Aramids area fall into two areas: the Diamines Production area (built in 1974) and the Phthaloyl Chloride (PCL) Production area (started in 1980). The Diamines Production area consists of Buildings 1221 and 1235. Building 1221 is the nitrator area where dinitrobenzene (DNB) is produced by reacting benzene with nitric acid in the presence of a strong sulfuric acid; Building 1235 is where phenylenediamines (PDs) are produced by reacting dinitrobenzene with hydrogen in the presence of a catalyst. The PCL production unit consists of three buildings: the Phosgene Area (Building 1074) where phosgene ($COCl_2$) is produced by reacting carbon monoxide (CO) with chlorine (Cl_2) in the presence of a catalyst; the packaging area (Building 1182); and the Phthaloyl Chloride (PCL) area (Building 1251) where either isophthaloyl chloride (OCL) or terephthaloyl chloride (TCL) is produced by reacting Phthalic acid either as isophthalic acid (I acid) or terephthalic acid (T-acid) with phosgene in the presence of dimethylfomamide (DMF) as a catalyst. Any wastes produced from the PCL and Diamines areas are sent to the WWTP.

10.3 Previous Investigations

The SWMUs identified as part of the RFI within the Aramids FA are described briefly here. More complete descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheet* (DuPont, 2002).

10.3.1 SWMU 33 (Manhattan Project-Related Area)

A portion of SWMU 33 is located in the northern part of the General Shops/Storage area of the Aramids FA (see Figure 10-2 or 10-3). This SWMU is an area that was used by the Manhattan Engineer District (MED) and the Atomic Energy Commission (AEC) from the 1940s through 1960s for radiological activities. SWMU 33 is being investigated as part of the ACOE FUSRAP program (created to address remaining radiological contamination), and two areas under investigation are located in the Aramids FA – Former Building 845 Area (including the wooden trough and ditch section that borders the northeastern and eastern portions of this area) and the F Parking Corral (the site of former Building 708). The building was removed. Several radiological surveys, as well as B Ditch remediation, have been completed for this former Building 845 area.

Beginning in 1942, DuPont entered into an agreement with the AEC to conduct manufacturing operations at two locations: the Blue Products area and the East area. The East area is discussed as part of the Miscellaneous FA (see Section 19). The Blue Products area was located adjacent to the Alcohol area at the southeastern border of the Fluoroproducts FA and in the northern portion of the Aramids FA. Beginning in April 1943, the Blue Products operations occupied an idle building known as the Glycerine Building (formerly used by the Alcohol Plant) while four small operating buildings in the area were completed. Production activities in the Blue Products area continued until February 1945. By June 1947, operations in the Blue Products area had ended, and most of the buildings in the area were rapidly dismantled. By February 1948, dismantlement was complete.

A report describing the SWMU 33 activities (Roy F. Weston, 2003) included the following conclusions:

- ❑ Building 845: Exposure from the residual radiological contamination in the building was substantially below the DOE protection guideline of 100 mrems/year – maximum exposure for DuPont employees was 9 mrem/year, and residual radioactive material remaining in the building did not pose a potential threat of future exposure.
- ❑ Parking Lot F: Low-level uranium contamination was detected in the soil.

In 1998, the ACOE removed nine drums of mixed waste and approximately 40 bags of PPE; the PPE had been left over from DOE investigation efforts. In 1999, DuPont completed building demolition. The ACOE investigation of this SWMU is ongoing, and reports describing these investigations are currently being developed by ACOE. (For more information about the status of SWMU 33, see Section 9.)

10.3.2 SWMU 39-6 (USTs)

Two former USTs were located in the Aramids FA. These tanks were used to store gasoline or diesel fuel and had no secondary containment or integrity testing. Both USTs have been decommissioned and removed. During closure activities, no soil sampling occurred. Based on EPA correspondence dated December 6, 1993, no further action is required for this SWMU.

10.3.3 SWMU 55-3 (Fill Deposition Area)

A fill area of about 2.27 acres runs along the eastern portion of the Aramids FA in the Elastomers area. There are no records concerning the origin of the fill. Based on Phase II RFI boring logs, the fill consists of orange-brown silty sand and gravel with concrete rubble, bricks, and occasional wooden debris. The SWMU was operated from around 1965 to 1975 (DuPont, 2002); review of aerial photographs suggests that the area was actively being filled since the 1940s.

According to the Phase II RFI, organics and metals were detected in soil at levels above screening criteria (DuPont, 1998). No further sampling was recommended because engineering and institutional controls exist. In and of itself, this SWMU does not warrant further evaluation; however, because it overlaps with the former location of a Hylene Plant, it was evaluated in the pathway analysis to determine potential impacts from the former operation of the plant.

10.3.4 SWMU 55-4 (Fill Deposition Area)

Another fill area of about 17.3 acres runs along the eastern edge of the FA (in the Parking Lot/Aramids area) and continues northward into the Fluoroproducts FA. This area was formerly part of the Whopping John marshland and was filled in before 1940. From 1945 to 1975, it was used for employee parking. In 1975, the PCL and Diamenes units were constructed on the former parking lot and are still in operation. There are no records concerning the origin of the fill. Based on the Phase II RFI boring logs, the fill consists of orange-brown silty sand and gravel with concrete rubble, bricks, and occasional wooden debris. According to the Phase II RFI, most soil samples had no VOC detections above the NRDCSCC, but a few metals and PAH exceeded the NRDCSCC. There were no exceedances of the IGW. Based on engineering and institutional controls, no further sampling was recommended.

SWMU 55-4 is not an area of interest because most of this area was formerly a parking lot with no known chemical processes; the PCL and Diamines units began operation over the SWMU 55-4 fill area only relatively recently.

10.3.5 SWMU 56 (Area of Elevated ODCB in B Ditch)

Historically, SWMU 56 received process wastes from operating areas and was hydraulically connected to SWMU 17 (the A Ditch). These ditches conveyed process waste from operating areas of the site to the wastewater basin. In 1973, SWMU 56 was reconfigured to convey non-process stormwater to the B Basin and was separated from the PWDS (SWMU 17). SWMU 56 was not included in the initial remedial activities of the A Ditch (SWMU 17) because SWMU 56 was not identified initially as part of the PWDS.

In July 1990, SWMU 56 was designated after elevated concentrations of ODCB were detected in the sediment at the base (approximately 500 linear feet) of the HPWDS (also known as the B Ditch). Additional delineation samples were collected during Phase II RFI, and an interim stabilization measure (ISM) was proposed for the ODCB portion of the B Ditch in the *RFI Phase II Report* (DuPont,1998).

The SWMU 56 ISM was completed in March 2000. The remedial action included mixing Portland cement and carbon in the ditch material prior to excavation and placement in the "A" Basin vault. A replacement conveyance system was installed, including an impermeable pipe and concrete basin storm water conveyance system.

Post-excavation soil samples collected during implementation of the ISM measured concentrations of ODCB above NRDCSCC. These samples were collected in the sidewalls adjacent to the remediated ditch, and within the center of the ditch beneath the excavation area. As requested by NJDEP, DuPont installed two wells to evaluate for the presence of DNAPL on top of the B/C confining layer adjacent to the post-excavation sample locations where the highest concentrations were detected. Recoverable DNAPL was not found in these wells.

Although SWMU 56 was remediated, soil beneath other sections of the ditch may also contain elevated ODBC concentrations; therefore, this area is considered in the pathway analysis.

10.3.6 SWMU 38 (Clean Water Injection Wells)

The site has several clean water injection wells that were used for injecting potable water from the site's potable water system into the deep aquifer unit (during times of low water demand) for storage and removal of this excess water during times of drought. This practice began in 1967 and continued until 1970 when site-wide water conservation measures resulted in decreasing water demand making this water storage practice unnecessary. One of these wells, H11-W01F (WS-3), is located in the southernmost tip of the Parking Lot/Aramids area; this well was not used for waste disposal but was designated a SWMU because it was identified as an injection well. In a letter dated March 25, 1993, the EPA agreed that no further action is required for this SWMU because it was initially mis-identified as a SWMU.

10.3.7 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the Aramids FA. Details about these SWMUs are presented in Section 4.3.1.

10.4 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the Aramids FA, areas were identified for further evaluation based on the reviews of historical area information, aerial photographs, existing data from various media, historical investigations, and existing remedial documentation.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❏ Chemical Process Database: The chemical process database was queried for the buildings that exist or existed in this FA.
- ❏ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- ❏ Soil Data: Soil analytical data for this FA are provided in Appendix D. Sampling locations are shown in Figure 10-4, and soil results are presented for chlorobenzene that exceeded criteria compared to NRDCSCC. Figure 10-5 shows soil results for chlorobenzene that exceeded criteria compared to IGW.
- ❏ Sediment Data: No sediment analytical data for this focus area are available.
- ❏ Surface-Water Data: No surface-water analytical data for this focus area are available.
- ❏ Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D.

Groundwater flow in the B Aquifer is generally towards the east. Groundwater flow and impacts in deeper aquifers are discussed on a site-wide basis in Section 4. Well locations are shown in Figure 10-6.

All available analytical data were reviewed for this FA. Because chlorobenzene was associated with the processes in the Aramids FA, it is used to illustrate the contaminant distribution. Concentrations of chlorobenzene in soil samples are shown on Figures 10-4 and 10-5; concentrations of chlorobenzene in groundwater are shown in Figure 10-6. As shown in Figure 10-6, elevated concentrations of chlorobenzene were detected throughout the Elastomers area, particularly near the former MVA and Hylene plants and in the historical trenches. Based on this review, the shallow groundwater in the Elastomers area should be evaluated further.

10.4.1 General Shops and Storage

The following areas were evaluated in the pathway analysis:

- ❏ Former Naphthalene Plant area (1917 map): This area was located west of the SWMU 33 building (see Figure 10-2).
- ❏ Former Combined Shop (1939 map): These shops were located on the western side of Building 1016 and to the north of Building 776 (see Figure 10-2). A lead shop and associated lead melt pot were located within this building complex.
- ❏ Former tar still (1915 map): A tar still and associated ASTs were located at the same locations as the combined shops. Therefore, the tar still must have been removed some time prior to 1939.

As shown in Figure 10-6, there are no groundwater analytical data in the vicinity of these areas. Therefore, DuPont recommends collecting groundwater samples in the vicinity of these areas to assess whether a source is present.

10.4.2 Elastomers/Isocyanates Area

The following locations in the Elastomers/Isocyanates area were evaluated in the pathway analysis:

- Former MVA plant(s) and associated ditches and building trenches and drains
- Former Hylene Plant and associated ditches and building trenches and drains
- Portion of SWMU 56 north of the former MVA and Hylene plants

The former MVA and Hylene plants were selected based on their operational history, waste disposal practices, and the lack of available groundwater quality data in the area. One monitoring well, J12-M01B, is located in the vicinity of the former MVA plant's building trenches and confluence with the B Ditch. After installation, this monitoring well contained NAPL, including elevated concentrations of PCE; TCE; cis-1,2-DCE; carbon tetrachloride; toluene; and chlorobenzene.

After the installation of another well (I12-M02B) northeast of the former Hylene Plant and within the A Ditch, NAPL was again detected. NAPL sampling results in 1994 and 1997 indicated elevated concentrations of constituents consistent with the compounds (e.g., nitrobenzenes) used and produced in the Naphthalene Intermediates area of the Triangle FA that drained to the A Ditch. In addition, high concentrations of DNT; ethylbenzenes; xylenes; chloroform; carbon tetrachloride; 1,1,2-trichlorotrifluoroethane; and PCBs were detected in the NAPL analysis. Most of these constituents are typical of the compounds used and produced in the Fluoroproducts FA.

DuPont recommends collection of groundwater samples and assessment of NAPL/DNAPL presence at additional locations near the former ditches and process building.

10.4.3 Parking Lot/Aramids Area

The following areas of interest were evaluated in the pathway analysis:

- Ditch from the Triangle FA to the Basins FA (SWMU 56A)
- Former location of DNT ASTs
- Former pond (1917 to 1940s)

Reviews of soil and groundwater data indicate very little spatial sampling coverage in these areas. DuPont recommends groundwater sampling in only the southern portion of the Parking Lot/Aramids area to increase spatial coverage. Groundwater in the vicinity of the former pond and DNT ASTs should be analyzed for DNT and former raw and production materials from the Acetylene and MVA plants.

Current operations were not evaluated since these operations are required to follow the DCPP if any releases occur.

10.5 Summary of Recommendations

Based on the pathway analysis, the following investigations are recommended:

- ❑ Collect groundwater samples in the vicinity of the combined shops, tar still, and naphthalene plant area to evaluate the potential effects on groundwater quality.
- ❑ Collect groundwater samples in the General Storage area, Parking Lot and Aramids area, and Elastomers area because there are currently insufficient analytical data to characterize groundwater quality in this area.
- ❑ Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the central portion of the Parking Lot and Aramids area and in the Elastomers area to assess groundwater quality and potential presence of DNAPL.
- ❑ Collect soil samples to characterize the distribution of soil in the SWMU 56 area that has elevated contaminant concentrations, which may be acting as a source to groundwater.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown in Figure 10-7.

11.0 FOCUS AREA – TRIANGLE

Preliminary assessment of the Triangle FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

DuPont recommends installing monitoring wells in areas near or downgradient of potential source areas where there is currently insufficient spatial coverage to delineate the extent of groundwater quality. Certain intermediates and final products were made primarily within specific areas, but process buildings were moved and various techniques were used for intermediate synthesis even within the same building over time. Chlorinated and aromatic VOCs and SVOCs were detected in groundwater samples in this FA; 1,4-dichlorobenzene, chlorobenzene, and nitrobenzene were the most widely detected compounds and had the highest reported concentrations. However, chlorobenzene had the highest average detections and is used to illustrate the contaminant distribution. Nitrated benzene compounds reflect the primary compounds produced in these areas, so nitrobenzene also is used to illustrate the contaminant distribution.

DuPont recommends collection of groundwater samples to evaluate groundwater quality and the presence of NAPL in the vicinity of the process wastewater ditches in order to assess these features as potential sources of groundwater contamination. In groundwater, nitrobenzene levels exceed 2% total aqueous solubility of nitrobenzene at one well, which prevents ruling out the presence of DNAPL. DNAPL is present in wells in the northwest corner of SWMU 8 and nitrobenzene concentrations also are elevated. Chlorobenzene exceeds 8% (0.044 g/L / 0.5 g/L) of its aqueous solubility in wells along the north-south ditch on the eastern side of the Triangle FA. The Triangle FA has few groundwater sampling locations. Given the elevated constituent concentrations, presence of DNAPL in nearby wells, and the network of process wastewater ditches in this area and waste, it is possible that other source areas are present in the Triangle FA. Therefore, additional sampling is recommended.

DuPont recommends collecting groundwater samples in the Bulk Storage area to evaluate potential effects of a reported o-chloronitrobenzene release on groundwater quality. In addition, groundwater sampling is recommended in other process areas of the Triangle Intermediates area, and around the New Products Building where MOCA was produced.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

11.1 Areas of Interest

The Triangle FA encompasses about 57 acres in the central portion of the site. It is bounded by the Aramids FA to the north, the TEL FA to the west, the Dyes and White Products FAs to the south, and the Miscellaneous and SWMU 8 FAs to the east (see Figure 11-1).

As shown in Figure 11-2, various areas are relevant to the Triangle FA history, including three SWMUs where remedial measures have been completed (see *Chambers Works FACT Sheet*, DuPont, 2002):

- ❑ SWMU 58: Former Sludge Pit
- ❑ SWMU 62: Aramids Nitrator Sump
- ❑ SWMU 17: Process Water Trench System (see Section 4.3.1)

Since remedial investigations/measures were completed, these SWMUs were not included in the pathway analysis for this FA. In addition, the Cafeteria, Construction, Warehouse/Transport, and Engineering/QC Labs/Admin areas were not considered for further evaluation in the pathway analysis because these areas have typically served as non-process areas and the deminimis quantity of materials associated with these areas.

The remaining historical areas are subject to pathway analysis to determine if additional investigations are necessary (see Figure 11-3):

- ❑ Triangle Intermediates Area
- ❑ Elastomers Area
- ❑ Engineering Area and Bulk Storage Area

11.2 History

The Triangle FA consists of former process buildings that have been included in several different businesses throughout the years. Major uses for these buildings include the production of intermediate compounds for dyes, elastomers, agricultural chemicals, and photographic chemicals, among others. Other uses include the production of end products such as “Neoprene”, “Adiprene”, “Hylene”, “Hytrel”, and “Viton.” The production facilities include various laboratories, store houses, warehouses, change houses, maintenance facilities, construction yards, and the Chambers Works rail road marshalling yard.

This section summarizes the history of the Triangle FA. A more comprehensive history is provided in the report titled *Chambers Works History* (DuPont, 1978) and a Executive Management summary prepared in 1980 (DuPont, 1980). Specific process data have also been found in the Chambers Works library and are included in the process history database.

11.2.1 Triangle Intermediate Area

The Triangle Intermediates Area is located within the western portion of the Triangle FA (see Figure 11-1). This area contained production buildings, tanks, and support areas used for the generation and/or purification of various intermediate compounds used in the creation of dyes as well as polymer products. Most of the buildings were installed sometime during the period 1915 though the 1940s. The general layout of the various process buildings within the Triangle Intermediate area is shown in Figure 11-2. Processes include the production of the following compounds: chloroanilines, dimehtlyaniline, nitroanilines, nitrobenzenes, toluidines, and nitrotoluenes. These chemicals were used for the production of various pharmaceuticals, agricultural chemicals, fibers, photographic chemicals, and other intermediates. Details about these and other compounds are presented in Appendix K.

Most all production has been removed from the Triangle Intermediates area. Based on the current building map shown in Figure 11-2, only the DMA Autoclave building, Zepple intermediates, and Dinitrotoluene production remain in this area. In addition, several shops and store houses also remain. The remaining buildings have been dismantled, and only the concrete foundations remain.

11.2.2 Elastomers Area

The term “elastomer” is often used synonymously with “rubber.” In short, elastomers are flexible polymers made by the polymerization of many small parts to make a single flexible unit. These synthetic rubbers are often much more stable and predictable than their natural counter parts and can be formed to design specifications using curing, or cross linking, agents as part of a two-part process. In general, there were five major businesses consisting of over 100 products that were highly specialized and unique to the rubber industry at the site. These included the following:

- ❑ Viton: High performance elastomers with outstanding temperature and solvent resistance.
- ❑ Adiprene: Castable liquids that can be cured to designed shapes that have high abrasion resistance.
- ❑ Hylene: Isocyanate cast and thermoplastic elastomer with properties unmatched by other commercial polyurethanes.
- ❑ Hytrel: Thermoplastic polyester polymers that bridges the gap between plastics and elastomers.

The Elastomers Area is located east of the Triangles Intermediates area, west of SWMU 8, south of Aramids FA, and north of the Transportation and Storage Area. Throughout its history, this area has hosted the production of several different products based on polymer chemistry.

Adiprene, Viton, and Rubber Chemicals

Neoprene was one of the earliest products created in this area. The origin of DuPont Neoprene dates from the early 1920s. Neoprene was produced from purchased cylinders of acetylene (and eventually acetylene produced on-site in Building 754). Acetylene was converted to monovinylacetylene (MVA) at Buildings 757 and 811. MVA was then reacted with chlorobutadiene and polymerized. This product was initially called DuPrene but was later renamed Neoprene. Although the Neoprene creation process changed through the years and eventually included organic peroxides and carbon tetrachloride, among others, the process remained largely unchanged. In about 1950, the Neoprene process was moved off-site and many of the original Neoprene buildings were converted to produce Viton and chemicals for curing rubber compounds.

In the 1950s, the manufacture of “Adiprene” urethane rubbers began. These high molecular weight polymers were quite rugged and well suited for truck tire and other similar uses. An interim plant was put into operation for the production of various glycols. Other miscellaneous productions were made including liquid urethanes, PTMEG-1000, purification of tertiary butyl anthraquinone, other miscellaneous distillations for site operations, and milling of rubber colors.

In about 1959, Jackson Laboratory developed a fluoroelastomer (Viton) capable of withstanding elevated temperatures, and interim facilities were installed in Semi-Works. Manufacturing required a monomer known as hexafluoropropylene; to supply sufficient quantities, interim facilities were installed in the New Products Building (745). During this time, Adiprene C and Adiprene L became important to Textile Fibers Department as an intermediate for Lycra spandex fiber. In 1961, a 10-million-pound capacity plant for the production of rubber chemicals, including Adiprene, was authorized in the New Products Building. In the mid-1960s, commercial-scale facilities for Viton manufacturing were installed.

In addition to producing end-products such as Viton and Neoprene, various rubber curing compounds also were created in this area. Rubber curing compounds were used as a two-stage process with the base materials. Once extruded or shaped to their particular need, these rubber curing chemicals would be used to cure, or cross-link, the rubber surface to create a durable product. The various rubber curing chemicals made at the site include MOCA (3,3'-Dichloro-4,4'-diamino-diphenylmethan), which is used to cure polyurethane rubbers. MOCA was reportedly produced in the western wing of the New Products Building (745A).

Approximately 162 million pounds of Neoprene were produced at the site from 1931 through 1949. Production was highest during the war years and reached almost 22 million pounds per year during this time. Viton and Adiprene continue to be manufactured at the site.

Hylene and Hytrel

DuPont began work in isocyanate chemistry around 1937 to 1940, when it established a broad patent protection for the reaction of isocyantes and active hydrogen compounds and polymeric materials with isocyanates. The area was originally called the Polyisocyanates area, but was renamed the Elastomers area in 1957. This area included the New Products Building minus the rubber colors milling operations.

The first Orchem (Organic Chemicals) isocyanates [hexamethylene diisocyanate (HDI) and diphenylmethane diisocyanate (MDI)] were made in Jackson Labs in the early 1940s. In 1946, the first Orchem 2,4-toluene diisocyanate (2,4-TDI) was prepared in Jackson Labs. Recognition that dimers of these chemicals might be used to control their reactivities led to renewed studies and uncovered commercial potential for toluene diisocyanate. In 1954, processes were chosen for the manufacture of hydrogen, carbon monoxide, and phosgene and were located at the former Neoprene area (MVA Buildings 757 and 811) of the site. The former Neoprene office and laboratory building became the administrative office. Three of the former Neoprene buildings were adapted for maintenance shops, product loading and warehousing, and product development. Construction began in 1955 and continued into 1956. The trade name “Hylene” organic isocyanates was chosen for the product.

Production statistics are not available for the Elastomers business unit. However, records indicate that 1957 saw strong growth in the elastomers business. In 1958, a continuous dinitrotoluene unit rated at 60,000,000 pounds annual was installed west of the Neoprene area (Building 1140, storage tanks 1144) to supply DNT to the elastomers toluene diisocyantes ("Hylene") plant. By the late 1950s, facilities had the capability to produce 35,000,000 pounds/year of elastomer products. A DNT plant was destroyed by fire on June 2, 1960, and was replaced with a new unit in August 4, 1960.

Most of the production has ceased within the Elastomers area. Viton continues to be produced at the New Products Building (745) although much of the building is vacant. Hylene was phased out of production in about 1980, and the production buildings in that area dismantled and/or transferred to the production of intermediates for the Aramids fiber business unit located to the north. Several offices and laboratories, such as the old Elastomers Office building, remain, but are unused for production purposes.

11.2.3 Engineering and Bulk Storage

Engineering Area

The Engineering and Bulk Storage Areas occupied the northwest corner of the Triangle FA. These areas served as support areas to the Triangle Intermediates Area as well as the site in general. No products were created at these locations. The Engineering Area contained buildings used to maintain the narrow gauge railroad used to haul products at the site.

This area is still used as a support area to the site. Buildings present today include the Car Repair Shop, Change House, Mechanical Instrument Shop & Office, Scale House, and storage buildings. Because the area was never used for chemical production or processes; it is not believed to be a source area, therefore, no additional investigation is recommended.

Bulk Storage Area

The Bulk Storage area was identified based on an interview with a site retiree . It was reported that tanker trucks and train cars were staged in this area to serve as bulk storage and/or loading and unloading for operation at the Hydrogen Reduction intermediate process. This area is particularly relevant in that 100,000 pounds of ortho-chloronitrobenzene was reported to have been spilled at this area in the mid-1980s. Although the product was removed, no post-removal sampling or impact evaluation was undertaken at this area. Therefore, further investigation is recommended.

11.2.4 Warehouse and Transport Area

The Warehouse and Transport area is located immediately south of the Elastomers Area, west of the Construction area, and east of the Laboratory and Offices area, and north of the White Products FA (see Figure 11-1). This area has historically been an area for the storage and shipping area for intermediate compounds, finished products, and drums.

The primary marshalling yard for broad gauge railroad traffic is also located in this area. This switch yard can be seen on the earliest aerial photograph and still exists to this day.

The plant's narrow gauge railroad can also be seen in this area feeding into the store buildings. This railroad was operated and maintained by the site for the hauling of materials around the plant site.

Currently, two large buildings remain in this area: the DP Warehouse Bay 10 and the Essential Materials Stores No. 3. The marshalling yard is also still present and activity used. The remaining buildings have been demolished down to their foundations. No further investigation is recommended.

11.2.5 Construction Area

The Construction Area is located on the eastern side of the Triangle FA, south of the Elastomers area, west of SWMU 8 and the Petroleum Laboratory, and east of the Transportation and Shipping area (see Figure 11-1). This area has historically been used for the fabrication of machinery, reactors, and buildings, among other things. These products were used at the site and were also shipped to other plant sites around the world. No chemical manufacturing processes were undertaken at this area.

The Construction area is not present on the 1939 site layout map. Several buildings appear on the 1952 plant layout map, and more appear on the 1963 plant layout map.

The only remaining building in this area is the Mechanical Construction Warehouse. All other buildings have been removed down to their foundations. Because this area is not a known production or disposal area, no further investigation is recommended.

11.2.6 QC Laboratory and Offices

The QC Laboratory and Administration area is a small area located within the center of the Triangle FA. No chemical production activities were undertaken in this area although several laboratories, garages, and a gas station have been identified on previous building layout maps.

Currently, the Chambers Works Quality Control Laboratory, Stores and Transport Change House, and Credit Union are located within this area. Therefore, no further investigation is recommended.

11.3 Previous Investigations

The SWMUs identified as part of the RFI within the Triangle FA are shown in Figure 11-2 and are described below. More complete descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheet* (DuPont, 2002).

11.3.1 SWMU 8

The western tip of SWMU 8 extends into the Triangle FA. SWMU 8 is a former landfill and is discussed in more detail in Section 13.

11.3.2 SWMU 58

SWMU 58 was a storage/staging area for sludges derived from the purification process of crude dichloroethane, dichloroaniline, o- and p-toluidine from the 1930s onward. The sludge was stored until enough sludge accumulated. The sludge was then loaded into narrow gauge rail cars with front-end loaders for iron recovery. The process continued until the late 1950s when DuPont changed the process from iron reduction to catalyst reduction. The gravel surface was removed down to the soil, and the area was covered with new stone in the late 1960s.

Soil at SWMU 58 was sampled during Phase II RFI and analyzed for 1,2-dichloroethane, 3,4-dichloroaniline, benzidine, m-toluidine and o-& p-toluidine. 1-2-dichlorothane and benzidine concentrations were below the NRDCSCC, and 3,4-dichloroaniline, m-toluidine, and o-& p-toluidine concentrations ranged from non-detect to 46 mg/kg. These three compounds do not have applicable criteria.

At the time of this previous study, no further action was recommended. However, it is within this area that a site retiree identified a large spill of ortho-chloronitrobenzene. This area will be advanced for further pathway analysis.

11.3.3 SWMU 62

SWMU 62 is located in an open operating building (Building No. 1221) as shown on Figure 11-2. Based on a DuPont letter to the EPA dated November 12, 1998, this SWMU was identified as a new SWMU to be investigated as part of the Phase III RFI. On October 30, 1998, the Wastewater Treatment Plant noticed that the outfall pH was falling to about 6. The WWTP personnel discovered low pH in the HPWDS and traced the source of the low pH to the Aramids/Nitrators building sump, which is approximately 20 feet from the HPWDS. The liner in the sump had developed a leak and allowed approximately 3,600 pounds of sulfuric acid to discharge underground. After the sump was cleaned, it was discovered that much of the sump bottom was missing.

Two soil samples and two groundwater samples were collected and analyzed for dinitrobenzene, nitrobenzene, benzene, dinitrophenol, nitrophenol, dinitrotoluene, nitrotoluene, toluene, xylene, chlorobenzene, and dichlorobenzene as part of the Phase III RFI. In soil, no constituent concentrations were above NRDCSCC. One sample had a benzene concentration (1.9 mg/kg), which slightly exceeds the Impact to Groundwater soil clean-up criteria (1 mg/kg).

Two temporary wells were installed near the sump: m-dinitrobenzene concentrations were the highest and ranged from 5,300 to 6,800 ug/L. The sump was filled with concrete, and no further action for soils was recommended.

11.3.4 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the Triangle FA. Details about these SWMUs are presented in Section 4.3.1.

11.4 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the Triangle FA five areas were identified for further evaluation. This conclusion was based on review of the historical area information, aerial photographs, existing data from various media, previous investigations, and existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The chemical database contains much data for the Triangle FA. Since no chemical processes have ever been done in the Warehouse and Transport Area, Engineering Area, and Construction Area these areas were not retained for evaluation.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this focus area is provided in Appendix D. Boring locations and chlorobenzene concentrations are shown in Figures 11-4 compared to NRDCSCC and on Figure 11-5 compared to IGW. Nitrobenzene concentrations are shown on Figure 11-6 compared to NRDCSCC and on Figure 11-7 compared to IGW.
- Sediment Data: There are no areas where sediment would be collected in this FA, therefore, no sediment samples were collected in this area.
- Surface-Water Data: There are no surface water features in this FA, therefore, no surface-water samples were collected in this area.
- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. These results are posted on Figures 11-8 and 11-9.

  Groundwater flow in the B aquifer is heavily influenced by the IWS system operating within the underlying C aquifer. There are four pumping wells within the C aquifer that reduce the head in the underlying aquifer and induce vertical groundwater flow through holes mapped within the BC confining unit. Groundwater flow in the B aquifer below the Triangle FA is predominantly eastward towards one of these mapped holes and ultimately is captured by the C aquifer pumping wells.

All available analytical results were evaluated. One of the most highly produced compounds in the Triangle FA was nitrobenzene, and this compound was commonly detected in the soil and groundwater samples. Therefore, nitrobenzene is used to illustrate the contaminant distribution. The detection of other compounds in samples was also considered.

In addition, the Warehouse and Transport Area, Engineering Area, and Construction Area are not considered for further evaluation in the pathway analysis because these areas have served as non-production areas since production began in 1917. Two areas of interest were retained for evaluation for the Triangle FA as were the ditch areas, all process areas, and the Bulk Storage area.

11.4.1 All Process Areas

As discussed throughout the pathway analysis evaluation, the following process areas within the Triangle FA warrant a pathway analysis:

- Triangle Intermediate Area
- Elastomers Area
- Bulk Storage Area

Based on the historical review of the area it is known that certain intermediates and final products were primarily made within specific areas. However, it is also known that process buildings were moved, improved, or destroyed and that various techniques were used for intermediate synthesis even within the same building over time. Therefore the process areas should be combined into one unit for pathway evaluation and the lack of data and specific analytes do not lend themselves well to pathway analysis.

In general, review of the compounds detected in soil and groundwater are consistent with the chemicals used within the Triangle Area. As shown in Figure 11-9, groundwater nitrobenzene concentration exceed 2% total aqueous solubility of nitrobenzene at well J10-M01B (0.042g/L / 1.9 g/L), which is typically indicative of the presence of NAPL. In fact, DNAPL is present in wells in the northwest corner of SWMU 8 and nitrobenzene concentrations are even higher. Chlorobenzene, used to illustrate the contaminant distribution at other focus areas, is also very high in wells along the north-south ditch on the eastern side of the Triangle FA. In this area, chlorobenzene exceeds 8 % (0.044 g/L / 0.5 g/L) of its aqueous solubility. However, the distribution of chlorobenzene seems to be aligned with the north-south ditch, whereas the nitrobenzene appears to be more isolated in the Ponsol Colors area and the Triangle FA, which can suggest these high detections are more local to the areas rather than homogenized from the north-south trending ditch system.

As shown in the figures, there are few soil and groundwater sample locations throughout the Triangle FA. Given the high concentrations and, in some cases, presence of DNAPL in nearby wells, in some areas, and the network of process water ditches throughout that were used for the disposal of process waste, additional investigation throughout the area is recommended.

11.5 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Triangle FA:

- Collect groundwater samples downgradient of the process wastewater ditches and process building trenches in the FA because there are currently insufficient analytical data to evaluate groundwater quality downgradient of these potential sources.

- Collect groundwater samples in the vicinity of the o-chloronitrobenzene release in the Bulk Storage area to evaluate the potential effects on groundwater quality.
- Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the Intermediates area, Engineering/QC Labs area, and Elastomers and Rubber Chemicals to assess groundwater quality and potential presence of DNAPL.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

Areas recommended for investigation are shown on Figure 11-10.

12.0 FOCUS AREA – BASINS

Preliminary assessment of the Basins FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

DuPont recommends sampling soil in the former basin drainage ditches to the northeast (BA4) and to the east of the basins area (BA5) to characterize soils. In addition, DuPont recommends sampling soil and groundwater in the area south of the remediated basins (BA6) to delineate possible impacts in soils. The main areas of interest in the Basins FA are located along the drainage paths, at its former and current discharge locations, and along its southern boundary. The basins themselves have been remediated. Closure certification reports were approved, and a postclosure groundwater monitoring program is in effect. Based on boring logs, it appears that samples were not collected deep enough to evaluate the potential impact of the historical use of a former drainage ditch in the northeast portion of the FA, so investigating this area is recommended to determine potential impact on sediment quality from historical basin flow.

No soil data are available to characterize the former drainage area (BA5) east of Basins FA; however, groundwater data for wells downgradient of BA5 were reviewed. Only arsenic and iron were detected above GWIIA. Historically (i.e., before the basin remediation), benzene, chlorobenzene, trichloroethene, and 4-chloroaniline were detected at levels above GWIIA in these wells. In addition, arsenic, iron, lead, and sodium have been detected above GWIIA in these wells. Because no characterization data are available for this area, soil sampling is recommended to determine the potential impact from historical basin flow to the soils underlying the fill. Based on constituent concentrations in surrounding wells, these soils may be contributing to the elevated concentrations of constituents in groundwater.

Soil samples collected within the boundary of BA6 (the area south of the remediated basins) were not deep enough to evaluate the underlying material and potential impact to soil from historical use. During a railroad construction project, excavation of a portion of BA6 noted visible contamination in three areas, and constituents in test pit samples were similar to average A Basin sludge concentrations, so additional soils were removed. Groundwater from wells throughout BA6 contained constituents historically related to the ditches and basins at levels above GWIIA criteria. Based (1) on impacts observed during the railroad construction project, (2) on soil analytical data comparable to A Basin sludge from test pits in this area, and (3)on constituents detected in groundwater from wells in BA6, additional soil and groundwater sampling is recommended to determine the extent of impacted soil.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

12.1 Areas of Interest

The Basins FA is located in the northwestern section of the site and is bounded by the Delaware River to the north, the Fluoroproducts FA to the west, the Aramids FA to the south, the WWTP FA to the east, and by Carneys Point to the northeast (see Figure 12-1)

Nineteen areas or features are pertinent to the Basin area history, as shown in Figure 12-2. These include three SWMUs where remedial measures are completed, so there is no need for a potential pathway analysis as part of this PAR. The three remediated SWMUs are as follows:

- SWMU 14: Former A Basin
- SWMU 15: Former B Basin (does not include the active B Basin waste management unit)
- SWMU 16: Former C Basin

Justification for not including the above SWMUs is discussed in Section 12.2.

The remaining areas are areas of interest that are either SWMUs or features that were identified during the aerial photograph review. These areas of interest are labeled with the prefix “BA” and are subject to pathway analysis to determine if additional investigations are necessary:

- B Basin Water Management Unit (BA7)
- SWMU 5 and SWMU 43: Landfill I and Former Unified Basin Outfall
- Original Basin Drainage Ditch through SWMU 5 (BA8)
- SWMU 60: Drum Disposal Area
- Former Discharge Location and Drainage Ditch near SWMU 60 (BA3 and BA4)
- Former Drainage Area (BA5) East of the Basins FA
- Area South of the remediated basins (BA6)
- SWMU 17: PWDS (see Section 4.3.1)
- SWMU 56A: Historical process water ditch system (HPWDS)
- SWMU 55-1, 55-3, 55-4: Fill deposition areas
- SWMU 12: WWTP storage area
- Former and Current Discharge Pipeline (BA1 and BA2)

In Figure 12-3, the areas of interest and SWMUs are labeled with their respective identification numbers.

More complete descriptions of SWMUs in the Basins FA were submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

12.2 History

Historically, surface water flowed in a stream named Whopping John Creek from the southeastern border of the site, through the SWMU 8 area and then into the Basins FA, and finally out to the Delaware River. Before 1970, the Basins FA was a low-lying marsh area. Process water, non-contact cooling water, and stormwater runoff flowed through the PWDS, into the basins, and then discharged to the Delaware River. The basins were dredged three times. In the 1970s, the current A, B, and C Basins were constructed. Over the course of time, storage of materials, discharges to the ditch system, deposition of fill, and changes to the discharge pipelines all created areas currently of interest within the Basins FA.

Originally, flow into the Delaware River was via a ditch (BA8) located to the northwest of the Basins FA. This ditch ran out through the remediated SWMU 5 area (Figure 12-3). By 1940, this ditch was no longer used. Flow to the Delaware River was either through SWMU 43 to a ditch to the northeast (BA4; Figure 12-3) or through a drainage area to the east (BA5; Figure 12-3) that flowed to Henby Creek, which then discharged to the Delaware River. By 1946, the BA5 surface water flow path no longer existed because the area was filled in. In 1957, a pumping station treated the acidic basin water (pH adjustment), and the water was discharged out a pipeline into the Delaware River to the northwest (BA1; Figure 12-3). A sluice gate was also added at the roadway that contained the waters in the basins from discharging to SWMU 43. This gate was used only during stormwater overflow conditions. By 1968, the sluice gate was removed, and this area was dammed. In 1975, severe weather destroyed the pipeline that was located in the river. The pipeline discharge location was moved to the end of the jetty and it is the current permitted outfall D001 (BA2; Figure 12-3).

The basins were dredged three times (1952, 1958, and 1965). These dredge spoils were placed in SWMU 8. The only documented dredge spoils volume was for the 1952 dredging which was estimated at 600,000 cubic yards.

Prior to 1970, process water, non-contact cooling water, and stormwater runoff flowed through the PWDS (see Section 4.3.1), into the Basins FA, which discharged to the Delaware River. As stated above starting in 1957, pH adjustment of these waters was completed prior to discharge into the Delaware River.

Starting in 1970, substantial changes were made to the Basins FA. A three-acre basin (C Basin) was constructed in the western portion of the area to act as a settling basin for process water generated by the tetraethyl lead (TEL) production area as seen on the 1974 aerial photograph. In the mid-1970s, a dike was constructed to form A and B Basins as seen on the 1979 aerial photograph. The road that currently separates the Former B Basin from the A Basin was the former dike. Details about other changes are described below.

12.2.1 SWMUs 14, 15, and 16: A Basin, B Basin, and C Basin

The A Basin was constructed as a 17.3-acre basin designed to receive process water and stormwater overflow. Water from the A Basin was then sent to the WWTP (constructed in 1975) for treatment of site process water. The B Basin was constructed as a 16.6-acre basin designed to provide settling and cooling of noncontact cooling water from the plant prior to discharge into the Delaware River. The B Basin also received effluent from the WWTP until November 1988. After 1988, effluent from the WWTP was pumped from the WWTP effluent trench directly to a mixing tank, bypassing B Basin.

The C Basin received TEL process waste from 1970 through 1988. In 1988, the C Basin was named SWMU 16 as part of the HSWA permit. In 1994, as part of the NJDEP-approved closure plan, lead-containing sediment from the C Basin (SWMU 16) was removed, treated, and disposed of as detailed in the *Certification of C Basin Closure dated February 28, 1995* (DuPont, 1999).

In 1988, DuPont and the NJDEP signed an ACO that required A and B Basins (SWMUs 14 and 15) to be closed. Between 1991 and 1996, material from A and B Basins was dewatered, treated by mixing with activated carbon and portland cement and consolidated within the boundaries of the basins. At this time, a 7.3-acre portion of the B Basin was converted to a permanent water management basin. The B Basin Water Management Unit (BA7) is described in the following section. In addition, a 2.8-acre vault was created on the northern portion of A Basin (Figure 12-1) to manage excavated materials from the basin and ditch remediation projects. The A Basin vault was closed in 2006. A closure report will be submitted to NJDEP in early 2007. Details of the basins closure process, the postclosure groundwater monitoring program and maintenance requirements is provided in the *A and B Basin Closure Certification/Remedial Action Report* dated March 19, 1997 (DuPont, 1997).

In 2002, a deed restriction was recorded with Salem County and an NFA and Covenant Not to Sue was issued by NJDEP for SWMUs 14, 15, and 16 (October 24, 2002). Therefore, with the possible exception of the B Basin Water Management Unit, a pathway analysis is not required for SWMU 14, SWMU 15, and SWMU 16.

12.2.2 B Basin Water Management Unit (BA7)

The B Basin Water Management Unit is used to manage stormwater and noncontact cooling water for the plant from the B Ditch (SWMU 56A; Figure12-2). The B Basin Water Management Unit is 7.3 acres, has an available water volume of 21.5 million gallons, is surrounded by earthen dikes, and has a subsoil base.

During closure of the A and B Basin, DuPont conducted sampling to characterize the soil below the sludge-soil interface at depths down to the first confining layer or to a depth of 6 feet, whichever was shallower. The purpose was to evaluate the impact of basin subsoil on the environment. The results of this sampling event and a risk assessment were presented in *Results of the A and B Basin Subsoil Sampling Program* dated August 31, 1992 (DuPont, 1992). The risk assessment evaluated the extent to which constituents present in the subsoil could enter the Delaware River, either through basin water discharge or groundwater migration. The risk assessment concluded that the existing subsoil beneath A and B Basins does not present a potential unacceptable risk to human health or the environment.

As stated previously, B Basin currently receives stormwater and noncontact cooling waters from the B Ditch (SWMU 56A). The Chambers Works stormwater system enters the B Basin via SWMU 56A at two primary locations: sample Spot 321, located at the southwestern corner of the basin, and at an undesignated spot located 200 feet to the east of Spot 321 (Figure 12-3). Surface water from the western and southwestern portion of the Site enters the basin at Spot 321, and surface water from the eastern and southeastern portion of the site enters the basin at the undesignated spot. Water is pumped from the north end of the basin at internal monitoring point DSN 322A and combined with the treated effluent from the on-site WWTP. The combined effluent from the basin and the WWTP discharges to the Delaware River via permitted outfall D001 (BA2; Figure 12-3).

Investigations at both Spot 322A and Spot 321 were conducted from 1999 to 2001. Residual concentrations of organics and metals were detected in the SWMU 56A surface-water sampling program (Spot 321) as well as at the outtake location (Spot 322A). These data are discussed in Section 12.3.

12.2.3 SWMU 5, SWMU 43, and Original Basin Drainage Ditch (BA8)

The original basin drainage ditch (BA8) that discharged into the Delaware River is shown in Figure 12-3. The discharge area, also known as SWMU 5B, has been the subject of numerous investigations and an approved interim stabilization measure (ISM), which was completed in 2002. The following paragraphs describe this area and summarize investigations and remediation work that has been completed for SWMU 5 and SWMU 43.

Since the operation at the site began nearly 90 years ago, portions of the site, including areas near the Delaware River, were used historically for disposal (i.e., outfall ditches and landfill areas). The SWMU 5 area (now SWMUs 5A and 5B) was once all uplands. However, due to inadequate shoreline maintenance at the site, the Delaware River naturally eroded the site's shoreline and encroached upon the upland areas where waste disposal had occurred. As the erosion continued, wastes in the SWMU 5 area became exposed to the environment.

DuPont has been investigating, evaluating, and conducting remedial actions within the SWMU 5 and SWMU 43 areas since 1994. The activities have included investigation of the uplands area of SWMU 5 (SWMU 5A), the beach/river side area of SWMU 5 (SWMU 5B), and SWMU 43. A slurry wall was installed in 1994 to 1995 to contain the former disposal area. While constructing this slurry wall, the western side was relocated from the original design location due to buried debris, including a significant number of old timbers. The location of these timbers coincided with the location of the original ditch outfall. This historical ditch outfall was sampled extensively as part of the 1998 to 1999 voluntary investigation. A *Technical Memorandum: SWMU 5* was submitted to the NJDEP in November 1999 summarizing investigations for SWMU 5 (DuPont, 1999).

Based on the findings from these investigations, an ISM was implemented in the SWMU 5 area. Remediation activities included the following:

- Removed sediment and stabilized SWMU 5B shoreline area.
- Installed the SWMU 5 permanent steel sheet-pile cutoff wall keyed into the BC confining unit and added protection from river erosion/scour.
- Established vegetation at SWMU 5 by creating uplands.
- Filled SWMU 43 with clean fill and established upland vegetation.

- Capped and restored the SWMU 43 area.
- Created 1.5 acres of intertidal aquatic habitat at Helms Cove Beach.
- Created two acres of freshwater wetlands at Henby Creek.

Remedial activities were conducted from July 2001 to May 2002. All remedial activities were conducted in accordance with the appropriate regulatory permits and correspondence.

A *SWMU 5 and 43 ISM Findings/Remedial Action Report* was submitted July 2002 and approved by NJDEP (DuPont, 2002). DuPont documented the limits of excavation and noted soil/sediment concentrations that were left in place. Additional discussion of these locations is presented in the Section 12.3.

12.2.4 SWMU 60 and Former Northeast Drainage Ditch (BA4) and Discharge Location (BA3)

SWMU 60 was discovered in 1995 during a field survey that identified the rusted hulks of approximately nine 55-gallon steel drums along a berm. The drums were corroded and crushed, but no visual evidence of liquids in or surrounding the drums was present. SWMU 60 is located in the area of the former northeast drainage ditch (BA4; Figure 12-3). Based on the aerial photograph review, this drainage ditch was used pre-1940 through 1962, after which it was filled in. The locations of this former ditch (BA4) and discharge point (BA3) are shown in Figure 12-3 and are visible on the 1940 aerial photograph . Adequate data to characterize SWMU 60 were collected as part of the Phase II RFI. Soil and groundwater data for SWMU 60 are further discussed in the pathway analysis. However, no data have been collected to characterize the former drainage ditch (BA4) or former discharge location (BA3).

12.2.5 Former Drainage Area (BA5) East of Basins FA

Based on a review of the 1940 aerial photograph, another former drainage area to the east of the basins area (south of BA4; Figure 12-3) was identified. This area discharged to Henby Creek pre-1940 until it was filled in by 1946. No soil data have been collected to characterize the former drainage area. However, groundwater data are available for this area and will be discussed in Section 12.3.

12.2.6 Area South of the Remediated Basins (BA6)

This area (BA6) includes sections of SWMU 17 (see Section 4.3.1), sections of SWMU 56A, the lower portion of SWMU 55-4, SWMU 55-1, SWMU 55-3 and SWMU 12 (see Figure 12-3). Although these areas are located outside the Basins FA boundary, they were part of the Basins in the past. Based on the aerial photograph review, the original footprint where water flowed through the basins extended to the southwest of the focus area as can be seen on the 1940 through 1946 aerial photograph. On the next available aerial photograph, 1951, this area begins to fill in with sediment and the ditches become clearly defined. To the southeast of the Basins FA, the original footprint where water flowed into the basins can be seen on aerial photographs from 1940 through 1944. On the next available aerial photograph, taken in 1946, this area begins to fill in with sediment, and the ditches become clearly defined. Also, portions of the ditches to the southeast (currently SWMU 17) were enlarged sometime between 1956 and 1974. These enlarged areas are visible in the 1959 and 1964 aerial photographs. This was most likely due to dredging activities that occurred in 1952, 1958, and 1962. The subsections below discuss the history of each of the SWMUs in this area.

BA6, SWMU 55-4, SWMU 55-1, SWMU 55-3 and SWMU 12

BA6 was formerly within the basin footprint including portions the ditch systems. Historically, water from the ditches flowed into the basins through this area. Currently, the western half of BA6 has been filled in and is either paved, covered with gravel, or is part of the Aramids FA. Sections of SWMU 56A and 17 also run along the southwestern focus area boundary to the inlet of B Basin. Near Spot 321, a wet marshy area with a small pond in the center exists. In addition, the lower portion of SWMU 55-4 is located in this area. Currently, the eastern half of BA6 area has been filled in and is either paved, covered with gravel, or is a remediated section of SWMU 17. In addition, SWMU 55-1, SWMU 55-3 and portions of the SWMU 12 IRM are located in this area (see Figure 12-3).

SWMUs 55-4, 55-1, and 55-3 are fill deposition areas. DuPont has no records of the origin of the fill placed in these SWMUs. These SWMUs were sampled as part of the Phase II RFI. These data are further discussed in Section 12.3. However, no data have been collected to characterize or delineate BA6, which underlies these SWMUs.

SWMU 12 is a former wastewater treatment pad located east of the former A Basin as shown in Figure 12-3. The pad was used to store lime that was used to neutralize the A Basin from 1960 to 1970. From 1970 to 1975, damaged containers contaminated with TEL were stored on the concrete pad. In 1976, the pad was used to store carbon involved in dewatering. SWMU 12 is situated over SWMU 55-1 and is covered with gravel.

A project was initiated to construct four new railroad spurs across the SWMU 55-1 and SWMU 12 area in 1989. Contaminated soils were encountered prior to construction. Three phases of soil sampling were conducted to help define the limits of excavation. The entire SWMU 12 area, along with additional areas beyond SWMU 12, were excavated as shown in Figure 12-4. The area was then backfilled prior to construction. A total of approximately 12,000 cubic yards of soil was removed and disposed of in the Secure C Landfill. Details of this activity are documented in a report titled *Interim Remedial Measures SWMU 12 WWTP Storage Pad*, dated February 1990.

Groundwater data were also reviewed for BA6 and are discussed in Section 12.3.

12.2.7 Former Discharge Pipeline (BA1) and Current Discharge Pipeline (BA2)

In 1957, a pumping station was installed to treat and convey basin water to the Delaware River via a pipeline. At that time, DuPont was required to adjust the pH of the acidic basin waters (by adding lime) as per state regulations prior to discharge into the Delaware River. Originally, the pipeline length was approximately 1,820 feet from the pumping station to the discharge point in the river (BA1; Figure 12-3). Basin water began being discharged to this location in 1957 and ended in 1975.

In 1975, a severe storm destroyed the pipeline that was out in the river. The pipeline discharge point (BA2; Figure 12-3) was then changed to the end of the jetty. The pipeline length is now 1,135 feet. This is the current permitted discharge point D001. This location is currently monitored under DSW Permit NJ0005100. Table BA-1 in Appendix D provides the current monitoring and frequency requirements for Outfall D001.

Other than required discharge to surface water monitoring at Outfall D001, no sediment or surface-water data have been collected to characterize these locations.

12.2.8 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the Basins FA. Details about these SWMUs are presented in Section 4.3.1.

12.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. Based on the historical assessments presented above, a potential pathway analysis is warranted for the following areas:

- ❑ B Basin Water Management Unit (BA7)
- ❑ SWMU 5, SWMU 43 and Original Basin Drainage Ditch (BA8)
- ❑ SWMU 60, Former Drainage Ditch (BA4) and Discharge Location (BA3)
- ❑ Former Drainage Area (BA5) East of the Basin FA
- ❑ Area south of the remediated basins (BA6)
- ❑ Former and Current Discharge Pipeline (BA1 and BA2)

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❑ Chemical Process Database: The only chemical process that occurred in the Basins FA was pH adjustment of the basin water prior to discharge. The chemical database does not contain any relevant data for the basins.
- ❑ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- ❑ Soil Data: Soil analytical data for this focus area are provided in Appendix D. Soil boring locations are shown in Figures 12-5 and 12-6. If data are discussed outside the boundary of the focus area, these data are available but are located in the other focus area tables.
- ❑ Sediment Data: Sediment analytical data for this focus area are provided in Appendix D. Sediment data for this focus area are related to the SWMU 5/43 remediation. No further discussion of these data are necessary. SWMU 5/43 has been remediated, and its remedial action report approved by NJDEP/EPA.

- Surface-Water Data: Surface-water analytical data for this focus area are provided in Appendix D. The surface-water data that are provided in these tables are related to the SWMU 5/43 remediation. No further discussion of these data is necessary. SWMU 5/43 has been remediated, and its remedial action report approved by NJDEP/EPA.

- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. If data are discussed outside the boundary of the focus area, these data are available but are located in the other focus area tables. Well locations are shown in Figure 12-8. Wells that are part of the closure and postclosure groundwater monitoring program for the A, B, and C Basins are also identified on this figure by call-out boxes. Groundwater flow, as shown in Figure 12-8, is generally to the southeast toward the IWS pumping well.

  Groundwater quality at seven wells located around the perimeter of the basins is monitored. Table BA-2 in Appendix D summarizes the frequency and analytical parameters for the closure and postclosure monitoring of the A, B, and C Basins. The wells in this program are shown in Figure 12-8 and are as follows:

  - G16-M02B
  - H13-M02B
  - H14-M01B
  - H16-P01B
  - K13-M02B
  - J16-M01B
  - L14-M01B

Based on a review of available soil and groundwater data , chlorobenzene was the most commonly detected constituent in these media and associated with most of the waste that was conveyed to the Basins. Therefore, chlorobenzene is used to illustrate the contaminant distribution.

12.3.1 B Basin Water Management Unit (BA7)

Surface water from the western and southwestern portion of the site enters the basin at Spot 321 (see Figure 12-3). In a May 20, 1999 letter, the NJDEP asked DuPont to determine the quality of the water in SWMU 56A at the point of discharge to B Basin (Spot 321). Monthly surface water sampling was conducted from January 2001 through December 2001. Fourteen constituents had concentrations that exceeded criteria throughout the sampling period. Further data evaluation was provided in the *Phase III RFI Report* dated April 2002 (DuPont, 2002).

Surface water from the eastern and southeastern portion of the site enters the basin 200 feet to the east of Spot 321. No sampling has been conducted at this location.

Water is pumped from the northern end of the basin at internal monitoring point DSN 322A (Spot 322A; Figure 12-3). In accordance with permit renewal requirements of the NJPDES Permit Number NJ0005100, an effluent characterization study was conducted at Spot 322A for a period of 18 months (February 1999 through December 2000) to determine whether changes to the existing DSW permit were needed (i.e., numerical limitations for additional pollutants) based on the effluent from the B Basin. Results of the study were submitted to the NJDEP Bureau of Point Source Permitting – Region 2 in February 2001.

Water pumped from Spot 322A is combined with the treated effluent from the on-site WWTP. The combined effluent from the basin and the WWTP discharges to the Delaware River via permitted outfall D001 (BA2; Figure 12-3).

Investigation results at both Spot 321 and 322A show that both organics and metals were detected. Spot 321 results were provided as part of the *Phase III RFI Report* (DuPont, 2002). Spot 322A results were submitted to NJDEP in a letter dated February 2001.

As stated above, inflow to B Basin is not limited to Spot 321 and the location 200 feet to the east. There are several other locations where stormwater enters the basin as runoff during precipitation events. Therefore, water quality within the basin can be potentially influenced by several inflows. In addition, B Basin may also be influenced by the IWS. Because B Basin is an unlined stormwater detention basin, water may recharge the underlying B Aquifer due to pumping of the IWS.

Currently, monitoring requirements are being met under NJPDES Permit Number NJ0005100. The BEE (DuPont, 2006) for the site has recommended a waterfowl study for the basin.

12.3.2 SWMU 5, SWMU 43, and Original Basin Drainage Ditch (BA8)

An interim stabilization measure was completed in 2002. Figure 12-7 shows the limits of the excavation, as well as, concentrations of remaining soil/sediments outside of the actual SWMU. The data indicate that these areas require further investigative work, sediment will be addressed as part of the BEE for the Delaware River outside of this PAR.

12.3.3 SWMU 60, Former Drainage Ditch (BA4) and Discharge Location (BA3)

The location of SWMU 60 (drum disposal area) and Phase II RFI boring locations are shown in Figure 12-5. Five of the six boring locations fall within the footprint of the drainage ditch (BA4). Phase II RFI boring logs and analytical data for SWMU 60 were reviewed. Boring logs indicated that the soil within SWMU 60 was fill material and was not consistent between boring locations. Groundwater was encountered between 1 and 8 feet at the six locations, and soil samples were collected immediately above the groundwater table.

Based on the boring logs, it appears that samples were collected properly for SWMU 60 characterization purposes but were not collected deep enough to evaluate the potential for impacted soils as a result of historical discharges from the basins. Therefore, additional investigations are recommended, including collection of sediment samples near the former discharge location (BA3).

12.3.4 Former Drainage Area (BA5) East of Basins FA

There are no available soil data to characterize BA5; however, groundwater data were reviewed in this area.

Groundwater data for wells, J16-M01B, K17-M01B and K17-M01C, located downgradient of BA5 were reviewed. Based on the most recent data – 2006 for J16-M01B and 1994 for K17-M01B and K17-M01C – only arsenic and iron were detected above GWIIA. Historically, pre-basin remediation, concentrations of benzene, chlorobenzene, trichloroethene, and 4-chloroaniline were detected above GWIIA in these wells although at much lower concentrations than detected at BA6 (discussed in the next section). In addition, historical concentrations of arsenic, iron, lead, and sodium were consistently detected above GWIIA in these wells.

Because no characterization data are available for this area, soil sampling is recommended to determine the potential impact from historical basin flow to the soils underlying the fill.

12.3.5 Area South of the Remediated Basins (BA6)

As stated previously, this area includes SWMU 17, SWMU 56A, SWMU 12, and SWMUs 55-1, 55-3, and 55-4. SWMU 17 and SWMU 56A are addressed in further detail in Section 4.3.1. The subsections below provide the pathway analysis for the remaining SWMUs.

BA6, SWMU 55-4, SWMU 55-1, SWMU 55-3 and SWMU 12

Soil samples were collected from SWMUs 55-4, 55-1, and 55-3 as part of the Phase II RFI. These sample locations are within the boundary of BA6. Based on boring logs, these samples were collected from fill material above the groundwater table. It appears that samples were collected properly for SWMU characterization purposes, but were not collected deep enough to evaluate the underlying material (BA6) and potential impact to soil from historical use.

As part of the railroad track construction project associated with SWMU 12, excavation of a portion of BA6 noted visible contamination in three areas. These areas are noted in Figure 12-4 as areas where additional excavation was completed. At the time, soil analytical results from test pit samples were compared to average A Basin sludge concentrations. These concentrations were found to be similar; therefore, additional soils were removed. These data were provided as part of the *Interim Remedial Measures SWMU 12 WWTP Storage Pad* dated February 1990.

Groundwater data were available for wells located throughout the footprint of BA6. These data confirm concentrations of constituents historically related to the ditches and basins exceed GWIIA criteria. The highest concentrations of organic constituents exceeding GWIIA criteria were detected in abandoned well I12-M02B and existing well K13-M02B. These groundwater analytical results are provided in Appendix D. It should be noted that groundwater from this area is captured by the IWS.

Additional soil and groundwater sampling is recommended to characterize the distribution of constituents in soil. This recommendation is based on soil observations during the railroad construction project, soil analytical data comparable to A Basin sludge from test pits in this area, and noted groundwater contamination in the wells located within BA6.

12.3.6 Former and Current Discharge Pipeline (BA1 and BA2)

Based on historical use and limited treatment of the basin water from the original pipeline, it is recommended that sediments be evaluated at this discharge location (BA1).

The current discharge location (BA2) has been operational from 1977 through present day. No further investigation of BA2 is proposed because monitoring requirements are being met under NJPDES Permit Number NJ0005100.

12.4 Summary of Recommendations

The basins themselves have been remediated. Closure certification reports were approved, and a postclosure groundwater monitoring program is in effect. A deed restriction has been recorded with Salem County and Covenant Not to Sue letter was signed by the NJDEP in 2002. Ongoing inspections are required for the basins, and a biennial report is required to document the inspection process and any required maintenance.

Based on the pathway analysis, the following is recommended for the Basin FA:

- ❑ Collect groundwater samples along the site perimeter in the former Drainage Ditch to evaluate groundwater quality and potential groundwater to surface-water pathways.
- ❑ Collect soil samples to characterize the distribution of soil in the former basin perimeter that has elevated contaminant concentrations, which may be acting as a source to groundwater.
- ❑ Evaluate sediment quality in the vicinity of the historical process wastewater outfalls along the Delaware River and at the discharge location from the former Drainage Ditch. The sampling will be performed as part of the perimeter investigation.

Areas recommended for investigation are shown in Figure 12-9.

13.0 FOCUS AREA – SWMU 8

Preliminary assessment of the SWMU 8 FA (SWMU 8) indicates that, beyond the remedial activities currently ongoing, there are no additional areas of interest that warrant additional investigation within SWMU 8. The conclusion is based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

Sampling and characterization of contaminant sources and distribution of constituents in soil and groundwater have been completed. Accordingly, a corrective measures study (CMS) is currently being developed. Based on the CMS, pre-design technology assessments to screen and confirm the effectiveness of selected remedial actions will be conducted at SWMU 8. After design parameters have been determined, appropriate remedial actions will be designed and implemented.

Shallow groundwater in the western portion of SWMU 8 has been impacted by historical disposal activities associated with SWMU 8 and with features such as ditches outside of SWMU 8. Investigation results confirm that the current groundwater IWS and site-wide perimeter monitoring program provide containment of constituents of concern and are effective in monitoring the conditions within SWMU 8, thus ensuring protection of human health and the environment.

DuPont will continue to remove DNAPL from the existing recovery well and monitor the additional wells during the monthly surveys. As recommended in the SWMU 8 RI (DuPont 2005), DuPont will continue to evaluate the integrity of the surface-water conveyance system that bisects Landfill A, will abandon one well, and will sample groundwater at nearby wells. DuPont also will continue the surface water monitoring program to determine if SWMU 8 constituents are entering the concrete stormwater pipelines buried beneath Landfill A. DuPont has completed two of the four rounds of sampling with both a dry event sample and a wet event sample collected in each round. The first two sampling rounds did not indicate that SWMU 8 constituents were significantly entering the concrete pipelines beneath Landfill A. DuPont will collect additional rounds of samples in 2006 and report the investigation findings in early 2007.

The full evaluation is presented in the rest of this section.

13.1 Areas of Interest

SWMU 8, also known as former Landfill IV, is a 140-acre area located in the eastern portion of the site. SWMU 8 is bounded by a railroad yard and the WWTP FA to the north, the Cogeneration FA to the northeast, the Miscellaneous FA to the south, the Praxair FA to the southeast, and the Basins FA to the west (see Figure 13-1). As shown in Figure 13-2, SWMU 8 currently includes Landfills A and B, several paved parking lots and roads, and various operating areas.

The following remedial activities are ongoing at SWMU 8:

- ❑ An evaluation of remedial alternatives through a RCRA Corrective Measure Study (CMS)
- ❑ DNAPL removal from an existing recovery well (L13-M01B) and monthly monitoring of a newly installed well
- ❑ Perimeter well sampling on the eastern side of SWMU 8 as part of the DGW requirements

13.2 History

Historically, SWMU 8 was the primary disposal site for solid, semi-solid, and some liquid wastes generated from the various operating areas of the plant from about 1940 to 1975. Over time, additional operating areas were constructed on top of waste fill. Several of the disposal activities were distinct enough to be designated as SWMUs (see Figure 13-2). Those SWMUs designated within SWMU 8 are as follows:

- ❑ SWMU 30: Landfills A and B, covering approximately 40 acres, are industrial waste landfills permitted by the NJDEP in 1975
- ❑ SWMUs 1, 2, 3, and 4: Former incinerator locations (Incinerator I, Incinerator II, Incinerator III, and Incinerator IV)
- ❑ SWMU 7: Landfill III
- ❑ SWMU 21: Thermal decontamination furnace (FR-65)
- ❑ SWMU 22: Multipurpose incinerator (FR-01)
- ❑ SWMUs 23 and 24: Chemical Waste Tank Area and Chemical Waste Container Storage Area
- ❑ SWMUs 39-4 and 39-7: USTs
- ❑ SWMUs 55-2, 55-5, and 55-6: Fill Deposition Areas
- ❑ SWMU 17: PWDS
- ❑ SWMU 56A: HPWDS
- ❑ SWMU 33: Manhattan Project

This entire area plus SWMUs are considered areas of interest (see Figure 13-3). More complete descriptions of these SWMUs were submitted in January 2002 in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

Between 1900 and 1930, the SWMU 8 FA was part of the smokeless gunpowder storage area associated with the Carneys Point Works. From the 1930s to 1974, Landfill IV (now known as SWMU 8) was used for the disposal of various wastes generated by the plant operating areas. These wastes included trash and general refuse; soil fill; construction debris and building rubble; discarded machinery and equipment; dredge spoils; bulk sludges and tars; basin and river dredgings; spent carbon and catalyst; bottom and fly ash; asbestos; drummed powder; paste; and liquid wastes, including waste oil and spent solvents chemicals.

The operation of Landfill IV was the responsibility of the Chambers Works Stores and Transport Department (S&T Department). The S&T Department used about 21 narrow-gauge sludge cars and 175 waste hoppers to collect the process waste materials from production areas for transport to the landfill. In addition, the S&T Department managed activities within the area, including recycling scrap metal and empty containers, incinerating liquid chemicals and solid waste, and disposing of non-process general trash. Bulk waste (including barrels and other containers) was dumped near the active face of the landfill as a means of fill emplacement. The wastes were then bulldozed into place, and heavy equipment was used to compact and spread the waste.

Site records indicate that the wastewater basin was dredged in 1950, and approximately 600,000 cubic yards of dredge spoils were deposited in SWMU 8; additional dredging was conducted in 1958 and 1965. By 1956, fill activities had replaced a majority of the Whopping John Creek marsh in the western portion of the area. Surface-water drainage through Whopping John Creek was diverted into a ditch that traverses the area, and a new road (Patrol Road) was constructed on an elevated dike. By 1964, Neoprene Road was constructed connecting the Chambers Works operating areas with Patrol Road. By 1974, the diked area north of Neoprene Road was filled in, and three diked areas were constructed. These diked areas now represent the footprints of current Landfills A and B (SWMU 30). During the continued filling of Landfills A and B, the surface-water flow in the area was channeled through two parallel buried concrete pipelines. The round pipeline conveyed overflow from the active disposal areas within Landfills A and B as part of the PWDS (SWMU 17). The rectangular pipeline consisted of rectangular concrete sections used to convey surface water from Whopping John Creek and surface-water ditches to the south as part of B Ditch (SWMU 56A).

Landfills A and B were issued a NJDEP Certificate of Approved Registration (#1713B) on September 15, 1975. The document described the permitted material for disposal in Landfills A and B as follows: "…elastomeric waste, oil, tars, silt, iron, hydroxide, aluminum hydroxide, and iron oxide sludges. No radioactive materials, septic tank waste, sewage sludge, or liquid or soluble chemicals may be disposed at this site." On March 8, 1983, the Certificate of Approved Registration was modified to allow the disposal of rubble, asbestos, bottom and fly ash, and plastic.

13.3 Previous Investigations

In 1989, a geophysical magnetometer study was conducted and revealed several geophysical anomalies representing ferro-magnetic materials in Landfill IV (Conoco, 1990). In 1992, a follow-up evaluation resulted in an estimate of 600,000 to two million buried drums in SWMU 8; this estimate has since been discounted because its basic assumptions were proven to be unfounded. A recent magnetometer study and soil borings advanced into areas of magnetic anomalies has proven that magnetic anomalies in SWMU 8 are not caused by densely packed steel drums, but rather by metallic building debris and other scrap metal (DuPont, 2005).

In 1994, the investigation of SWMU 8 began during the implementation of a Phase I RFI. At the request of the NJDEP and EPA, the SWMU 8 investigation was accelerated independent of the RFI process. From 2003 to 2004, investigations were conducted to collect data to further delineate the horizontal and vertical extent of contaminants in all media and to refine the site conceptual model for the SWMU. Grab water results from Landfill A and B borings contained constituent concentrations above the GWIIA, although the water samples represented water in the landfills and not from the underlying B Aquifer.

The objective of the L13 DNAPL investigation as part of the RI activities was to determine if the recovery of DNAPL could be enhanced. To achieve the objective, a cone penetrometer testing (CPT) sampling program was completed in the L13 well area to determine the NAPL thickness and the structure of the confining unit (clay). The structure of the clay and thickness of the NAPL were plotted to determine the most probable location for an additional recovery well. A new recovery well was installed in 2005; however, no NAPL has been observed in the well.

During the 2004 investigation, three wells (L12-M03B, M10-M02B, and M10-M01B) were installed specifically for NAPL recovery. Approximately 0.075 liters of DNAPL was recovered from the L12-M03B location. No additional NAPL or DNAPL has been observed in any of these wells since 2004.

In late November 2004 as part of Phase IV RFI field activities, lithologic gamma logging of well L12-M01D was completed (DuPont, 2005). A smear of oil was observed on the bottom of the gamma probe during removal. Based on this observation, a bailer was lowered to the bottom of the well, and approximately 0.5 liters of DNAPL was removed. Follow-up evaluations have not produced additional NAPL volume. Follow-up gamma logging and cement bond logging were completed in January 2005, and results were inconclusive (DuPont, 2005). The well was not sampled in 2005 because of a blockage. This well will be abandon and replaced in early 2007.

DuPont submitted the SWMU 8 RI report to the NJDEP and EPA in February 2005 (DuPont, 2005). In 2006, based on EPA comments, DuPont installed additional B Aquifer wells at the perimeter of Landfills A and B. These wells were installed to fill vertical spatial data gaps (per NJDEP observation of a red spot on 1972 aerial photograph and assess potential contamination migration pathways from SWMU 8 into the shallow portions of the B Aquifer. Two B Aquifer wells, one shallow and one deep, were installed to evaluate groundwater quality. Stratigraphic data also were collected to verify the current hydrogeologic model. In particular, borings and current cross-sections based on the RI results suggest the absence of a B/C confining unit in the eastern portion of SWMU 8 underlying a portion of Landfill A and virtually all of Landfill B. DuPont submitted the SWMU 8 RI Report Addendum to the NJDEP and EPA in June 2006.

In discussions between DuPont and NJDEP on February 22, 2006 and May 1, 2006, NJDEP requested that DuPont complete a RCRA CMS for SWMU 8 to identify and evaluate potential remedial alternatives. Landfill A is full, but not closed pending resolution of the underlying SWMU 8 remedial action with the NJDEP. Landfill B is permitted for additional capacity of industrial waste, but currently is not allowed to be used until SWMU 8 remedial action is addressed to the satisfaction of NJDEP. In early 2006, a permit renewal report was submitted to the NJDEP Solid Waste division for Landfills A and B.

13.3.1 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the SWMU 8 FA. Details about these SWMUs are presented in Section 4.3.1.

13.4 Pathway Analysis

The pathway analysis for SWMU 8 was completed as part of the RCRA Remedial Investigations that occurred in 2003 to 2006. The specific goals of the SWMU 8 investigations were to 1) verify that the landfill units are stable, 2) evaluate the nature and extent of waste materials, 3) determine concentrations of constituents in soil and water, and 4) confirm the absence of intact drums. The SWMU 8 investigations were developed based on a review of the historical aerial photographs and plant maps, previously collected data, and interviews with current and former employees (DuPont, 2005 and 2006). The figures and tables for the SWMU 8 evaluation have been provided to the NJDEP in both hardcopy and HazSite deliverables via the SWMU8 RI and RI Addendum and were not copied into this report.

As described throughout this section, no additional areas of interest within SWMU 8 were determined during the PAR evaluation.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements:

- Chemical Process Database: Chemical processes did not occur in SWMU 8. The only operations conducted in this area was dredge and waste disposal and filling. The chemical process database does not contain any relevant data for SWMU 8.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this focus area were presented and discussed in the SWMU 8 RI and RI addendum (DuPont, 2006 and 2005) and have not been resubmitted in this report. Figures from previous reports have not been included in this report; refer to the SWMU 8 RI and RI addendum for a more complete description of sampling activities and results.
- Sediment Data: No sediment analytical data have been collected.
- Surface-Water Data: Surface-water analytical data currently are being collected as part of the SWMU 8 surface-water work plan (DuPont, January 2006). No data are being provided in this report pending concurrent sampling A report summarizing findings and analytical data will be provided to the NJDEP in the second quarter 2007.
- Groundwater Data: Groundwater analytical data for SWMU 8 were provided in the SWMU 8 RI and Addendum (DuPont, 2006 and 2005). Groundwater has been evaluated for SWMU 8 in the RI and Addendum and results are summarized below.

13.4.1 Fill and Soil

Based on previous investigations (DuPont, 2005 and 2006), the landfill units are stable and do not contain intact drums. The fill in the landfills primarily consists of bulk materials and construction debris including dredged materials from the A and B Basins. The constituents most frequently detected in Landfill A materials included benzene, chlorobenzene, 1,2-DCB, and hexachlorobenzene. The constituents most frequently detected in Landfill B included benzene, chorobenzene, 2,4-DNT, 2,6-DNT, hexachlorobenzene, and PCE. DNAPL was not detected at the base of the landfills; a low permeability stratum exists at the bases that likely inhibits downward migration of impacted water into the underlying B Aquifer.

In addition to the characterization of the fill contained in these landfills, the fill outside of the landfill boundaries, but still within SWMU 8, were characterized. Fill materials were encountered in all borings from ground surface to depths of about 20 feet below ground surface. The fill materials encountered varied from mixed construction/building materials, wood fragments (timbers), sand, glass, brick, and a black sludge-like material. No void spaces were observed, but some very soft uncompacted fill areas were noted. Soil samples were collected at intervals that had elevated instrument readings, or at the bottom of the fill interval. The analytical results indicated compounds detected above NRDCSCC. The highest frequency of detection was noted for benzene, chlorobenzene, 1,2-DCB, 1,4-DCB, N-nitrosodiphenylamine, nitrobenzene, and 1,2,4-trichlorobenzene.

In many of the sampled locations, the constituent concentrations and fill type varied with depth, indicating a heterogeneous fill distribution. The heterogeneous nature observed in the fill was consistent with historical records indicating random placement of various fills over time throughout SWMU 8.

13.4.2 Groundwater Flow and Quality

The October 2005 groundwater elevation contour map for the B Aquifer shows inward hydraulic gradients along the site boundaries, including SWMU 8. A groundwater depression is apparent in the B Aquifer north of SWMU 8 due to pumping well M14-R02C and to a thinning or absence of the B/C confining unit.

The site-wide containment system extracts groundwater from the C Aquifer near SWMU 8. Groundwater in the B Aquifer flows to the east in the western portion and to the west in the eastern portion of SWMU 8 due to the influence of the C Aquifer extraction wells. In the western portion, due to the absence of the B/C confining unit in the eastern portion of SWMU 8, groundwater in the B Aquifer is drawn to the east from areas outside the SWMU and down into the C Aquifer where the confining unit is absent.

Shallow (B Aquifer) groundwater has been impacted in the western part of SWMU 8 by historical activities outside of the SWMU. The western portion of the B Aquifer, in general, has the highest concentrations of constituents, most likely from impacts of a major portion of the process water ditch system that runs north-south and is located due west of SWMU 8. Impacts from Landfill A may also account for the northern portion of groundwater contamination, in addition to the DNAPL zone and the “red” zone (in the 1972 aerial color photograph). The primary constituents detected in groundwater include benzene; chlorobenzene; 1,2-dichlorobenzene (ODCB); 1,2,4-trichlorobenzene; nitrobenzene; aniline; and 4-chloroaniline.

Constituent concentrations along the eastern and southeastern portions of SWMU 8 were either nondetect or below GWIIA. Groundwater in the B, C, and D Aquifers is captured by the IWS, extracting groundwater in the C and D Aquifers. Groundwater in the E Aquifer is captured by recovery well J05-W01E and supply well R15-W01E.

13.4.3 DNAPL

Groundwater constituent concentrations, boring logs, and well data indicate that DNAPL is limited to the northwestern part of SWMU 8 near the L13 and M12 well clusters. Additional delineation and recovery efforts to increase DNAPL recovery focused on the L13 area and other areas of the site (DuPont, 2005 and 2006). A new recovery well (L13-M02B) was installed based on the delineation efforts, but to date has not had significant recoverable DNAPL.

13.5 Summary of Recommendations

Based on the pathway analysis, no additional areas of interest within SWMU 8 were determined during the PAR evaluation beyond the remedial activities currently ongoing.

DuPont will continue to remove DNAPL from existing recovery well L13-M01B and monitor the newly installed well, L13-M02B, during the monthly surveys.

An evaluation of remedial alternatives (CMS) is underway. Following the CMS, pre-design technology assessments to screen and confirm the effectiveness of selected remedial actions will be conducted at SWMU 8. After design parameters have been determined, appropriate remedial actions will be designed and implemented.

Additional investigations are not required in the SWMU 8 FA.

14.0 FOCUS AREA – WASTEWATER TREATMENT PLANT (WWTP)

Preliminary assessment of the Wastewater Treatment Plant FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

DuPont recommends collecting soil samples to characterize the distribution of soil in the A Ditch sections within SWMU 55-1 that has elevated contaminant concentrations and that may be acting as a source to groundwater. This recommendation is also described in the Basins FA (see Section 12).

DuPont recommends expanding the SWMU 8 boundary to include the 1952 dredge spoils disposal area beneath the Rail Yard so that future investigations in this area are included in the SWMU 8 Corrective Measures Study. The 1952 fill deposition area associated with SWMU 8 covers the southern half of the Rail Yard area, but has not been addressed in previous investigations of SWMU 8 because it is shown outside of the SWMU border.

DuPont recommends revising the location of SWMU 55-2 and including it as part of SWMU 8 so that future investigations in this area are included in the SWMU 8 Corrective Measures Study. SWMU 55-2 is an area of historical fill deposition identified during the 1988 RCRA Facilities Assessment conducted by EPA. Soil samples collected at SWMU 55-2 during the Phase II RFI had no detections of site constituents above criteria. Judging by historical aerial photographs and plant layout maps, the Phase II RFI samples were collected in the portion of SWMU 55-2 that was not an area of historical fill deposition – the historical fill area associated with SWMU 55-2 lies entirely within SWMU 8.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

14.1 Areas of Interest

The Wastewater Treatment Plant (WWTP) FA is about 80 acres in the central portion of the site and is bounded by the Carneys Point FA to the north, the Cogeneration FA to the east, the Basins FA to the west, and the SWMU 8 FA to the south (see Figure14-1).

The WWTP FA has been divided into three subareas: SWMU 18 (WWTP), Rail Yard Area, and Western Area. Several of these areas have been previously investigated and/or remediated. These areas are listed below and included only in the history section of this focus area (see Figure 14-2):

- ❑ SWMU 17: PWDS (sections within SWMU 18)
- ❑ SWMU 18: WWTP

- SWMU 18A: WWTP Pump Pit
- SWMU 39-8: USTs
- SWMU 55-1: Fill Deposition Areas
- SWMU 12: WWTP Storage Pad

The following remaining areas in the WWTP Focus Area are discussed further in the pathway analysis section:

- Railyard Area (Dredge spoils area associated with SWMU 8)
- SWMU 55-2 (Fill Deposition Area)
- SWMU 17 (PWDS) in Western Area adjacent to Basins

These areas are shown in Figure 14-3. More complete descriptions of these SWMUs were previously submitted in January 2002 in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

14.2 History

The WWTP FA was originally part of Carneys Point Works. Activities in this area involved the production of nitrocellulose and smokeless gunpowder and are discussed in detail in Section 20. During the peak of World War I production Carneys Point Plant 3 and a portion of Plant 2 were located in this area, as well as storage bunkers, roads, and narrow-gauge railways. The area was abandoned and most of the buildings were removed shortly after the end of the war because of the decreased demand for nitrocellulose and smokeless gunpowder.

14.2.1 SWMU 18 (WWTP)

From 1919 to 1970, the only activity in the area was related to six nitrocellulose storage bunkers. These structures were removed before 1970 during initial land clearing for construction of the WWTP. In 1971, DuPont began building a wastewater treatment pilot plant to comply with the DRBC implementation of the 1965 CWA. Additions to the plant were constructed between 1972 and 1975, and wastewater treatment began full-scale operations in 1975. During construction, fill was brought in as a construction base to increase the ground elevation roughly 5 feet. As a RCRA Part B operating unit, the WWTP was designated as SWMU 18. Beginning in the 1990s, the WWTP was upgraded to meet more stringent environmental regulations (e.g., a third secondary clarifier and a tertiary treatment step were added).

Currently, the WWTP accepts aqueous nonhazardous and RCRA hazardous waste (characteristic and listed D, F, K, P and U codes). Industries that send waste to the WWTP include chemical, pharmaceutical, petroleum refining, paints and coatings, primary metals production, galvanizing, electroplating, printed circuit board manufacturing, and utilities. Waste sources include the following:

- Process waste
- Equipment cleaning and decontamination waters

- ❑ Pollution control systems
- ❑ Spent acids and caustics
- ❑ Spill control and stormwater control systems
- ❑ Condensates
- ❑ Groundwater, leachates, and remediation systems
- ❑ Biosludges
- ❑ Discarded or off-specification products

The primary system neutralizes the acidic waste streams, pre-treats outside wastes, precipitates out heavy metals, adds polymers to assist in settling of solids, and removes sludge prior to secondary treatment. In the secondary system, bacteria, carbon, and air work together to begin the biodegradation of the organics in the waste streams. Some nonbiodegradable organics are adsorbed on the surface of the carbon in the secondary treatment.

The tertiary system further treats the wastewater stream by biodegradation and carbon adsorption. The quality-treated effluent from the tertiary is then mixed with cooling water at the outfall and discharged into the Delaware River. Solids from the Secondary and Tertiary systems are filtered through a filter press and sent to the Chambers Works Secure Landfill.

For inorganics, the waste treatment process involves the following:

- ❑ Neutralization and precipitation
- ❑ Heavy metal pretreatment/metal hydroxide precipitation
- ❑ Sulfide pretreatment

For organics, the waste treatment process involves the following:

- ❑ Powder activated carbon treatment (PACT) – biological and carbon adsorption treatment
- ❑ Steam stripping/organic recovery (completed in TEL FA)
- ❑ Phase separation (completed in TEL FA)

Organic wastes that are accepted include priority pollutants, ignitable constituents (D001), halogenated and non-halogenated solvents, multi-phase, and organic acids.

The DuPont Secure Environmental Treatment (SET) Wastewater Treatment Facility is currently operated in accordance with NJPDES Permit No. NJ00051000, which became effective October 1, 2005, and expires on September 30, 2010. The operating areas of the WWTP are paved with asphalt, and stormwater in the area is conveyed to the treatment system. Because this SWMU is an operating unit and has adequate cover in place, this SWMU was not retained as needing further evaluation. SWMUs located within SWMU 18 are discussed below.

SWMU 18A (WWTP Pump Pit)

SWMU 18A is an open, fiberglass-lined, concrete waste conveyance system that is part of the WWTP (SWMU 18). According to construction engineers, steel sheet piling was driven to a depth of approximately 40 feet around the pump pit to provide sidewall stabilization prior to construction. The pump pit is approximately 150 feet long, 15 feet wide, and 7.5 feet deep. Liquid wastes to be treated in the WWTP are discharged into the pump pit.

During the A Ditch remediation, wastewater was detected flowing from the pump pit to the ditch. Two holes were discovered in the bottom of the pit, caused by erosion of the fiberglass lining and the concrete as a result of wastewater injection. As part of the Phase II RFI (DuPont, 1998), one soil, one clay, and one groundwater sample were collected from each of the four borings at SWMU 18A. Soil and clay sampling results indicated that all metal, VOC, SVOC, and pesticide constituent concentrations were below NRDCSCC and IGW soil cleanup criteria. Groundwater sample results indicated that several constituents (benzene, chlorobenzene, 1,2-dichlorobenzene, aniline, and 4-chloroaniline) were detected at concentrations above the GWIIA. These concentrations in groundwater are believed to be related to site-wide presence of these constituents rather than directly related to SWMU 18A. The site-wide evaluation is presented in Section 4.0.

The pump pit was repaired in 1991, thereby eliminating a potential source to groundwater. This SWMU was not retained as needing further evaluation.

14.2.2 Rail Yard Area

Prior to 1919, the Rail Yard area was associated with Carneys Point Works Plant 2 as the location of a solvent alcohol recovery unit and associated structures (see Section 20). From 1919 to 1952, there was no activity in the area. In 1952, this area received dredge spoils from the dredging operations in the wastewater basins to the west. This dredged material was primarily deposited in the SWMU 8 FA to the south, but a portion was placed in the Rail Yard area, as defined by an earthen dike delineating the dredge spoils area. Additional fill placement occurred in the area between 1953 to the mid-1960s. The initial Rail Yard was constructed in 1968 and expanded between 1969 and 1974. An interceptor well (Q13-R01CD) was installed around 1970, and the southern portion of the area began to be used as the railroad laydown area prior to 1976. This area is currently used as a railcar storage yard and as a laydown area for railroad equipment (railroad ties, spikes, rails, and related hardware). There are no SWMUs currently associated with this area, but it shares a common fill deposition history with SWMU 8, which is directly south. Therefore, this area is evaluated in Section 13.

14.2.3 Western Area

Before 1919, the Western area was associated with Carneys Point Works Plant 3 and included the central portion of the plant, specifically the powerhouse, main office, and various operating buildings, shops, and associated structures. These buildings were removed around 1920, leaving behind only foundations. The other significant feature in the area was related the wastewater basin (see Section 12) located to the west.

The entire area remained inactive until the 1930s when a sodium bulk storage area was constructed in the southern portion of the focus area to supply sodium to the TEL manufacturing area. The sodium was stored in this area to separate it from other site operating areas because of its reactive properties and potential safety concerns. The sodium bulk storage operation used an oven to heat rail cars of sodium to a molten state. The rail cars containing molten sodium were then transported to the TEL FA. Two aboveground fuel oil tanks located 100 feet to the northwest (Buildings 1012 and 1007) were the fuel source for the sodium oven. Sodium storage in this area ceased in 1956.

Since 1946, a salvage yard and excess machinery yard appears in aerial photographs as located directly east of the sodium area. This area was used to store excess machinery and equipment from other areas of the site pending re-deployment or disposal. After 1956, this salvage yard was enlarged to include the former sodium area. Five ASTs located at the southern end of the salvage yard, formerly used to store sodium, were converted to store oil and petroleum. Drainage from the salvage yard entered a surface water body directly south of the oil storage tanks (in the SWMU 8 FA). This surface water body flowed into the A Ditch (SWMU 17) until it was filled in around 1974 during construction of the WWTP.

Buildings in this area include the following:

- The Sandblast Building (Building 1082) was constructed around 1956 directly north of the salvage yard to conduct sandblasting, and has been used continually since that time.
- Buildings 1007 and 1012 were ASTs located north of Plant 1 Road in the Western area. Building 1007 consisted of two ASTs that contained benzene and methyl alcohol, located here from 1951 to around 1974. No information was available about AST construction, spill history, or the presence/absence of secondary containment.
- Building 1012 consisted of two ASTs that contained oil and petroleum, located here from 1951 to around 1980. These tanks were surrounded by a secondary containment berm from 1951 to 1974. Based on historical information, the ASTs are believed to have been used originally as part of the sodium storage area. No information was available about construction or spill history of the ASTs.

Several SWMUs are in this area, including a portion of the WWTP pump pit (SWMU 18A), sections of the A Ditch (SWMU 17), a RCRA Part B-permitted oil/water separator (SWMU 27), a former UST location (SWMU 39-8), a former WWTP storage pad (SWMU 12), and two areas of historical fill deposition (SWMU 55-1, 55-2). SWMU 18A was discussed previously. The remaining SWMUs in the Western area are discussed here.

SWMU 27 (Oil/Water Separator)

SWMU 27 is a RCRA-permitted oil/water separator associated with the DuPont Secure Environmental Treatment Wastewater Treatment Facility. This unit is currently operated in accordance with NJPDES Permit No. NJ00051000, which became effective October 1, 2005, and expires on September 30, 2010. Because SWMU 27 is an operating unit, no further investigation of this area is being proposed at this time.

SMWU 39-8 (UST)

Nineteen USTs existed at the site and were designated as SWMU 39. One UST within SWMU 39 (SWMU 39-8) was formerly located in the WWTP FA and was used to store gasoline and/or diesel products. The UST was removed and no evidence of leakage was observed. In a letter dated December 6, 1993, the EPA agreed to no further action for this SWMU. Therefore, no further investigation of this area is recommended.

SWMU 12 (WWTP Storage Pad)

SWMU 12 is a former WWTP storage pad located east of the former A Basin within SWMU 55-1. SWMU 12 is addressed as part of the Basins FA (see Section 12).

SWMUs 55-1 and 55-2 (Fill Deposition Areas)

SWMUs 55-1 and 55-2 are areas of historical fill deposition identified by the 1988 RFA conducted by the EPA and based on an aerial photograph review. DuPont investigated these areas in the Phase II RFI (DuPont, 1998):

- SWMU 55-1
  Most of SWMU 55-1 was occupied by Carneys Point Plant 3 in 1919. In aerial photographs taken between 1956 and 1975, fill deposition was visible at the southern end of SWMU 55-1, and was visible at the north end of this SWMU between 1970 and 1975 during construction of the WWTP pump pit, rail unloading spot, and the A Ditch reconfiguration. DuPont has no records of the origin of this fill. Based on the Phase II RFI boring logs, the fill in SWMU 55-1 consists of orange-brown, silty sand and gravel with concrete rubble, bricks, and occasional wooden debris. SWMU 55-1 is addressed further in the pathway analysis section of the Basins FA (see Section 12).

- SWMU 55-2
  SWMU 55-2 was occupied by Carneys Point Plant 3 in 1919. Historical fill deposition may have occurred before plant construction in 1918, but no confirmation is available. The location of SWMU 55-2 was mapped during the RFA conducted by the EPA based on the 1940 aerial photograph. A portion of SWMU 55-2 lies within the WWTP FA, and the remainder lies within the SWMU-8 FA. The recent review of aerial photographs and plant layout maps using ArcView indicates that the actual location of fill deposition associated with SWMU 55-2 is different from the location mapped previously – the actual location of the fill of SWMU 55-2 is slightly south of the mapped location and is entirely within SWMU 8. Fill deposition occurred here between 1964 and 1974. The portion of SWMU 55-2 within the WWTP FA sampled during the Phase II RFI had no evidence of fill deposition. No further investigation was proposed in the Phase II RFI.

14.2.4 SWMU 17 and SWMU 56A

Sections of SWMU 17 and SWMU 56A are located within the WWTP FA. Details about these SWMUs are presented in Section 4.3.1.

14.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the WWTP FA, three areas were identified for further evaluation based on reviews of historical information, aerial photographs, existing data from various media, historical investigations, and existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

- Rail Yard Area: Dredge spoils area associated with SWMU 8
- SWMU 55-2: Fill Deposition Areas
- SWMU 17 (PWDS) in Western Area adjacent to Basins

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: Chemical process data were available.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data for this FA are provided in Appendix D. Boring locations area shown in Figures 14-4 and 14-5.
- Sediment Data: Because there are no areas where sediment could be collected in this FA, no sediment analytical data are associated with this FA.
- Surface-Water Data: There are no surface-water features in this FA, therefore no surface water analytical data are available for this FA.
- Groundwater Data: Groundwater analytical data for this FA are provided in Appendix D. Well locations are shown in Figure 14-6. Groundwater flow, as shown in Figure 14-6, is generally to the interior of the area and toward pumping well M14-R01CD.

  Groundwater analytical data from abandoned wells in this FA are provided in Appendix D. Well locations are shown in Figure 14-6.

  Groundwater grab sampling using temporary well points is provided in Appendix D.

All analytical data were reviewed for the FA. A primary manufacturing component at the site was chlorobenzene, and this compound was most commonly detected in the soil and groundwater samples. Therefore, chlorobenzene is used to illustrate the contaminant distribution.

14.3.1 Rail Yard Area: Dredge Spoils Area Associated with SWMU 8

The 1952 fill deposition area associated with SWMU 8 covers the southern half of the Rail Yard area. This area of fill deposition has not been addressed in previous investigations of SWMU 8 because it is shown outside of the SWMU border. There are no soil analytical data and no B Aquifer analytical data for site constituents. It is recommended that the outline of SWMU 8 be extended to include the area of fill deposition (dredge disposal) within the Rail Yard area, and that future investigations in this area be included in the SWMU 8 Corrective Measures Study scheduled for agency submission in early 2007. Investigation of the remaining Rail Yard area (north of the fill area) is not recommended because this rail yard was used only for storage – no loading was conducted.

14.3.2 SWMU 55-2

SWMU 55-2 is an area of historical fill deposition identified on a 1940 aerial photograph during the 1988 RCRA Facilities Assessment conducted by EPA. Soil samples collected at SWMU 55-2 during the Phase II RFI had no detections of site constituents above criteria. Judging by historical aerial photographs and plant layout maps, the Phase II RFI samples were collected in the portion of SWMU 55-2 that were not areas of historical fill deposition – the historical fill area associated with SWMU 55-2 lies entirely within SWMU 8. It is recommended that the border of SWMU 55-2 be corrected to include the area of fill deposition associated with SWMU 8, and that future investigations in this area be included in the SWMU 8 Corrective Measures Study scheduled for agency submission in early 2007.

14.4 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the WWTP FA:

- ❑ Collect soil samples to characterize the distribution of soil in the "A Ditch" sections of SWMU 55-1 that has elevated contaminant concentrations, which may be acting as a source to groundwater.
- ❑ Refine the location/boundaries of SWMU 55-2 based on review of aerial photographs and GIS data.

Areas recommended for investigation are shown in Figure 14-7.

15.0 FOCUS AREA – COGENERATION

Preliminary assessment of the Cogeneration FA indicates that, aside from the planned investigations associated with the ecological investigation of SWMU 42 (Hendy Creek), no additional investigations are necessary. This recommendation is based on the results of reviewing historical processes, aerial photographs, and previous analytical results in soil and groundwater, as well as a pathway analysis. These analyses and reviews were conducted consistent with applicable regulations and guidelines.

Details of the review and evaluation are presented in the rest of this section.

15.1 Areas of Interest

The Cogeneration FA is about 66 acres and is located in the northeast section of the site. It is bounded by the Carneys Point FA to the north, the WWTP FA to the west, the Praxair FA to the south, the SWMU 8 FA to the southwest, and Route 130 along the site perimeter to the east (see Figure 15-1).

The Cogeneration FA contains three SWMUs as shown in Figure 15-2. More complete descriptions of these SWMUs were submitted in January 2002 in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

SWMU 50 (Asbestos Disposal Area) was previously investigated and remediated. This SWMU is presented in the history section but was not considered for evaluation in the pathway analysis because further investigation is not warranted.

The following areas in the Cogeneration FA are discussed further in Section 15.3:

- ❑ SWMU 32A: Cogeneration Facility Area A
- ❑ SWMU 32B: Cogeneration Facility Area B
- ❑ SWMU 42: Henby Creek

Based on the pathway analysis, additional investigation is needed at SWMU 42 (Henby Creek). Henby Creek will be further investigated as part of a site ecological investigation (DuPont, 2006).

Areas of Interest for this focus area are shown in Figure 15-3.

15.2 History

Prior to 1919, the Cogeneration FA was the location of Carneys Point Works Plant 2, which was involved in the production of nitrocellulose and smokeless gunpowder. This area included the central portion of the plant, which housed the powerhouse, main office, as well as various operating buildings, shops, and associated structures. These buildings were removed around 1920, leaving behind only foundations (see Figure 15-2). The area was inactive from 1920 to 1974. Vegetative cover in this area gradually transitioned from grasses and shrubs to uplands forests.

In 1974, construction began on the Explosion Hazards Laboratory (EHL) in the northern portion of the focus area and is located on a portion of SWMU 32B. This laboratory performs R&D and is still operating today. The charter of the EHL is to provide experimental data to define the reactive process hazards associated with new and existing processes and products throughout the corporation on a world-wide basis. Experiments ranging from small-scale calorimetry to large-scale explosions are conducted in specialized facilities designed to ensure that tests can be carried out in a safe, controlled manner.

Also in 1974, fill material was placed in two areas along the southern portion of the focus area. This placement was coincident with construction of the wastewater treatment facility, located a few hundred yards to the west. Based a review of aerial photographs and recent excavations, fill material was believed to be construction debris (concrete rubble and timbers). The area was inactive after 1975 until construction of the Cogeneration facility in 1991.

In 1990, the construction of a 262-megawatt pulverized coal-fired Cogeneration facility was proposed by the Chambers Cogeneration Limited Partnership (CCLP). It was constructed in 1991 on approximately 27 acres in a portion of SWMU 32. The plant began commercial operations in 1994, providing electricity to Atlantic City Electric and DuPont. The Cogeneration facility also provides steam to the site.

15.2.1 SWMU 32 (Cogeneration Facility Areas A and B)

SWMU 32 lies northeast of the WWTP on-site and is divided into two areas, SWMUs 32A and 32B. Buildings in this area were used to store explosives, primarily nitrocellulose and gunpowder, produced at the Carneys Point Works. Materials may also have included those materials used in the production of nitrocellulose and gunpowder (e.g., ether, nitrotoluenes, nitric acid, amines, nitroglycerine salts, sulfuric acid). Explosive materials were removed around 1920. Operations ceased at the Carneys Point Works in 1975. After 1979, the area was used for blast testing. No products or chemicals were produced in this area. Currently, SWMUs 32A and B contain the Cogeneration facility and Explosives Hazards Laboratory, both of which are active.

SWMU 32A was investigated in June 1990 and January 1991 prior to the construction of the Cogeneration facility. Sampling was conducted to confirm that complete removal of all explosives material did indeed occur (around 1920) in this location. SWMU 32A investigation results showed that all constituent concentrations were below the NRDCSCC. In a letter dated April 28, 1992, DuPont obtained approval from the EPA that the soil investigation was complete. Therefore, SWMU 32A is not a potential area of concern, and no further evaluation is necessary. The details of the investigation are provided in the reports titled *Chambers Works SWMU #32 Soil Investigation* (DuPont Engineering, 1990) and *Report for the Subsurface Investigation SWMU #32 at the DuPont Chambers Works Facility* (OHM Remediation Services Corporation, 1991).

SWMU 32B also was investigated in June 1990 and January 1991 prior to the construction of the Cogeneration facility. Sampling was conducted to confirm that complete removal of all explosives material did indeed occur (around 1920) in this location. The investigation results are further discussed in Section 15.3. Based on these results, DuPont proposed that no further remedial activities were warranted for this area. The details of the investigation are provided in the reports titled *Chambers Works SWMU #32 Soil Investigation* (DuPont Engineering, 1990) and *Report for the Subsurface Investigation SWMU #32 at the DuPont Chambers Works Facility* (OHM Remediation Services Corporation, 1991).

Soil excavation was necessary in the SWMU 32 area to prepare for the construction of the Cogeneration facility. During excavation activities, personnel detected an odor emanating from the soil. The soil was sampled to determine the odor source; investigation results indicate slightly elevated levels of dimethyl phthalate and di-n-butyl phthalate. It was concluded that these compounds were responsible for the odor. The low soil concentrations measured permitted no further action and were deemed suitable for a sanitary landfill or at the site. The details of this investigation are included in the report *Field Report, Cogeneration Orthodichlorobenzene Sampling* (DuPont, 1991).

In addition, a thick, viscous liquid was observed during excavation activities. The liquid was sampled to determine proper disposal methods. Results of TCLP sampling indicate that the material was nonhazardous. Trace amount of VOCs (including di-n-butyl phthalate) and lead were found in the sample. Details are provided in the report *Field Report, Co-Gen Liquid Sampling, Chambers Works Site* (DuPont, 1991).

15.2.2 SWMU 42 (Henby Creek)

SWMU 42 is a creek that originates off-site and traverses southeast to northwest, south of the former Carneys Point Works. Henby Creek represents the primary surface-water drainage pathway from Carneys Point and, as such, is discussed in detail in the Carneys Point FA section of this report (see Section 20). This evaluation of Henby Creek addresses the portion of the creek within the Cogeneration FA. SWMU 42 was investigated during the first three phases of the RFI. Sediment and surface-water data are further discussed in Section 15.3.

15.2.3 SWMU 50 (Asbestos Disposal Area)

SWMU 50 contains the rubble associated with the demolition of the former Carneys Point Works Powerhouse. The open foundation was filled with rubble, including piping and equipment covered with asbestos. The area was discovered at a test pit excavation during Cogeneration facility construction and consisted of two distinct piles.

Asbestos was the only waste material associated with this area. After asbestos debris removal, visual inspection and site air monitoring verified that the area was free of asbestos. In a letter dated March 25, 1993, the EPA agreed to no further action for SWMU 50. This decision was based on EPA’s review of the *Current Conditions Report* dated December 18, 1992.

15.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: No chemical processes occurred in the Cogeneration FA; therefore, the chemical database does not contain any data for this area.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- Soil Data: Soil analytical data tables and figures for this focus area are available in referenced reports as noted in the preceding and following sections.
- Sediment Data: Sediment analytical data for this focus area are provided in Appendix D. Boring locations are shown in Figure 15-4. Sediment data for this focus area are related to the SWMU 42 investigation.
- Surface-Water Data: Surface-water analytical data for this focus area are provided in Appendix D. Sampling location areas are shown in Figure 15-5. The surface-water data that are provided in these tables are related to the SWMU 42 investigation.
- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. Wells are located in the B Aquifer and are shown in Figure 15-6. Groundwater flow, as shown in Figure 15-6, is generally to the southwest (toward the IWS pumping well).

  Groundwater quality in the B Aquifer has been monitored periodically since 1990. The wells are shown in Figure 15-6 and are listed below with the years they were sampled in parentheses.

  - R15-M01A (1990-1995)
  - T14-M01A (1990-1991)
  - U12-M01A (1990-2005)
  - U14-M01A (1991-1995)

As shown in the data tables, only VOCs and SVOCs detected were methylene chloride, bis(2-ethylhexyl)phthalate and one occurrence of 1,2-dichlorobenzene. All of the concentrations only marginally exceed GWIIA. Similarly, metals were present at very low concentrations comparable to off-site locations (e.g., lead; see Figure 15-6).

15.3.1 SWMU 32 (Cogeneration Facility Areas A and B)

As stated previously, DuPont obtained approval from EPA that the soil investigation was complete. No further remedial activities at SWMU 32A were necessary.

Soil samples were collected and analyzed for PPL VOCs, SVOCs, and metals. Nine metals, two VOCs, and four SVOCs were detected in the samples. All VOCs and SVOCs detected were at concentrations below NRDCSCC. Only one metal (arsenic) was detected greater than the NRDCSCC. The data are presented in *Area B Soil Investigation Summary*, DERS, June 14, 1993. The arsenic concentration is representative of typical background concentrations. This elevated concentration was detected in the subsurface soil, which has limited potential exposure. Exposure is also prevented through the use of institutional controls that are in effect. No further remedial activities at SWMU 32B are necessary.

15.3.2 SWMU 42

In SWMU 42 (Henby Creek), sediment and surface-water samples were collected from locations along the creek. This section discusses only those sample locations within the Cogeneration FA – three sediment samples and five surface-water samples. The remaining sampling results are addressed in the Carneys Point FA (see Section 20).

Sediment sampling results indicate exceedances of ecological benchmark concentrations for total metals; 1,2-dichlorobenzene; 1,4-dichlorobenzene; and SVOCs. Sediment sample locations are presented in Figure 15-4.

Surface-water sampling results indicate exceedances of surface-water criteria concentrations for total iron, lead, mercury, and aluminum. VOCs and SVOCs were detected in the sediment samples. Bis(2-ethylhexyl)phthalate was the only constituent detected at levels that exceeded screening concentrations. All of the surface-water samples had detections of bis(2-ethylhexyl)phthalate, with exceedances of the concentration in samples 42-B-1, 42-B-2, and P4-42-2. Surface-water sample locations are presented in Figure 15-5.

15.4 Summary of Recommendations

Evaluation of Henby Creek (SWMU 42) will be completed as part of the Baseline Ecological Evaluation (BEE) for Carneys Point.

16.0 FOCUS AREA – PRAXAIR

Evaluation of the Praxair FA indicates that there are no areas of interest and no additional investigations are necessary. This conclusion is based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

No chemicals were processed, stored, or transported in the Praxair FA, and no process wastewater trenches were located in this FA. In addition, only two organic compounds were detected in groundwater above applicable criteria, and these compounds are not representative of site-related constituents. Some metals were detected in groundwater, but the concentrations are consistent with off-site concentrations.

Details of the review and evaluation are presented in the rest of this section.

16.1 Areas of Interest

The Praxair FA is named as such because it is the current location of a Praxair Corporation facility. Praxair is a provider of industrial gases, including atmospheric, process and specialty gases.

Praxair FA is located in the easternmost section of the Chambers Works plant and borders SWMU 8 on the west (see Figure 16-1). The Praxair FA is bounded by the SWMU 8 FA, which includes Landfill A to the southwest, and Landfill B to the north-northwest, the Cogeneration FA and associated plant to the northeast. Shell Road (Route 130) and the Off-site FA (baseball fields) are due east of the Praxair FA. The Praxair FA encompasses approximately 67 acres.

Based on the aerial photograph review, property transaction records, and available data, no areas of interest were identified for further evaluation in the Praxair FA.

16.2 History

The Praxair FA was part of the Carneys Point Powder Plant 2 during World War I. During WWI, buildings were placed into operation as Plants 1, 2, 3, and 4 (see Figure 16-2). The land was idle from the 1940s until the 1980s. The land that Plant 2 formerly occupied, in part, became the location of Cogeneration plant (see Section 15) and, in part, the Praxair facility.

The land occupied by the Praxair FA has been leased by DuPont to Union Carbide since November 20, 1989. Union Carbide later became Linde and then Praxair. DuPont also supplies water for fire fighting and cooling to the facility and handles the sanitary sewage and industrial wastewater, which are treated through the on-site WWTP.

As defined in the HSWA permit, the EPA included the SWMU 8 eastern boundary as part of the Praxair FA. Because SWMU 8 does not actually extend into the Praxair FA, it is not discussed in this section.

The current activity in the Praxair FA is converting natural gas to carbon monoxide and hydrogen. The carbon monoxide is supplied to the phosgene operation in the Aramids FA, and the hydrogen is supplied to the diamine operation in the Aramids FA.

16.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. For the Praxair FA, no areas were identified for further evaluation. This conclusion was based on the historical area review, aerial photograph evaluation, review of existing data from various media, review of historical investigations, and review of existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: No chemicals were processed in the Praxair FA. The chemical database does not contain any relevant data for this area.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area. No trenches were located within this focus area. The only utilities are located aboveground along Patrol Road. Utility maps for the currently operating Praxair facility were not available for review.
- Soil Data: No soil sampling data were available for the Praxair FA.
- Sediment Data: No sediment analytical data were available for this focus area.
- Surface-Water Data: One open ditch is present on the southwestern side of the focus area (see Figure 16-1). This ditch is the principal conduit for Praxair stormwater. The outfall location is being investigated as part of the SWMU 8 RFI work plan for surface water (*SWMU 8 Work Plan for Surface Water*, DuPont, 2006). Praxair stormwater is managed under the Chambers Works DCPP plan. The SWMU 8 surface water investigation is currently ongoing and is expected to be completed by the first quarter 2007.
- Groundwater Data: Shallow groundwater in the Praxair FA flows from east to west or from off-site toward Praxair due to the influence of the IWS pumping wells (see Figure 16-3).

  Groundwater analytical data for VOCs, SVOCs, pesticides, herbicides, metals, and TICs for the active B Aquifer wells are provided in Appendix D. Additionally, because the B/C clay layer is missing in some areas and the C Aquifer is under pumping conditions, the B and C Aquifers are strongly connected within this focus area. Therefore, C Aquifer well analytical data also were reviewed. Active and abandoned well locations are shown in Figure 16-3.

  Most of the data reviewed were presented in the SWMU 8 RI report and associated addendum (DuPont, 2005 and 2006). Additionally, in compliance with the NJPDES-DGW Permit No. NJ0105872, the following site-wide perimeter wells are located near this focus area and are monitored:

- U08-M01B (off-site)
- R09-M01B
- R09-M02C
- R09-R01D

Analytical results were available for the B Aquifer and C Aquifer; the review of these results indicates that only two compounds were detected in shallow groundwater above GWIIA: methylene chloride and bis-2-(ethylhexyl)phthalate. Metals (total) detected above GWIIA included arsenic, aluminum, antimony, beryllium, iron, manganese, nickel, and lead.

16.4 Summary of Recommendations

The land in the Praxair FA was idle from the cessation of Carneys Point Powder Works Plant 2 operations until the construction of the Praxair facility in the early 1980s. No SWMUs were identified with the area, and concentrations of VOCs and metal in groundwater are not representative of historical operations at the site. Therefore, based on the pathway analysis, additional investigations are not required in the Praxair FA.

17.0 FOCUS AREA – CURRENT OFF-SITE PROPERTIES

Evaluation of the Off-Site FA indicates that there are no areas of interest and additional investigation is not necessary. This conclusion is based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

The Off-Site FA includes Off-Site Property #1 and Off-Site Property #2. Off-Site Property #1 was divided into three areas – the Ballfield, the 1919 Shipping Area-1, and the Well Field. The Ballfield area was used as a residential trailer park before DuPont purchased it in 1975. The 1919 Shipping Area-1 was purchased by DuPont in 1945, donated to Carneys Point Township in 1987, and has no areas of environmental concern. The Well Field area is currently a truck stop. Before selling the property, DuPont conducted an assessment and concluded that there were no environmental concerns.

Off-Site Property #2 was divided into two areas – the Country Club Area and the 1919 Shipping Area-2. The Country Club Area is currently occupied by a golf course. Before 1918, DuPont had constructed a labor camp of several dozen temporary barracks, a YMCA, mess halls, and other structures. By 1940, little evidence of the camp remained and, in 1960, DuPont conveyed the land to the Sakima Country Club.

No manufacturing processes occurred in this FA. In groundwater at the Ballfield area, only low concentrations of methylene chloride and PCE have been detected above GWIIA criteria, but are not related to the site.

Details of these reviews and evaluations are presented in the rest of this section.

17.1 Areas of Interest

The Current Off-Site Properties Focus Area (Off-Site FA) is located to the east of the current Chambers Works manufacturing area and is not part of any current plant operations. The Off-Site FA was subdivided into Off-Site Property #1 and Off-Site Property #2 (see Figures 17-1 and 17-2). These areas were included for evaluation in this report because these areas were identified on the 1919 Carneys Point Works layout map as being associated with the Chambers Works Complex.

Based on the aerial photograph review, property transaction records, and available data, no areas of interest were identified for further evaluation in the Off-Site FA.

17.2 History

The Off-Site FA includes Off-Site Property #1 and Off-Site Property #2.

17.2.1 Off-Site Property #1

Off-Site Property #1 is approximately 48 acres and is located north of Deepwater Village on the eastern side of Route 130. Based on evaluation of available information, Off-Site

Property #1 was divided into three distinct areas – the Ballfield, the 1919 Shipping Area-1, and the Well Field:

Ballfield

The Ballfield area is the current location of the Chambers Works baseball fields, and five groundwater monitoring wells are installed on this parcel. This is the only area of Off-Site Property #1 that is currently owned by DuPont. The area was used as a residential trailer park prior to the DuPont purchase in 1975.

1919 Shipping Area-1

The 1919 Shipping Area-1 was identified on the 1919 layout map as a “Shipping Area” with narrow gauge rail lines connecting 15 structures believed to be smokeless powder bunkers. Based on the 1940 aerial photograph and the property transaction record, it is possible that the structures on the 1919 map may have been proposed but never constructed based on lack of physical evidence. This property was purchased by DuPont in 1945 and donated to Carneys Point Township in 1987. There are no areas of environmental concern in this area.

Well Field

The Well Field area is currently occupied by a truck stop. It was purchased by DuPont in 1940 and used as the location for several potable water supply wells until about 1960 when the wells were sealed. One remaining monitoring well was sealed before DuPont sold the property in 1997 to the current truck stop owners. In 1997, DuPont conducted an assessment of the property prior to the sale and concluded that there were no environmental concerns.

17.2.2 Off-Site Property #2

Off-Site Property #2 is approximately 173 acres and is located about one mile north of Off-Site Property #1, also on the eastern side of Route 130. Based on evaluation of available information, Off-Site Property #2 was divided into two distinct areas – the Country Club Area and the 1919 Shipping Area-2:

Country Club Area

The Country Club Area is currently occupied by a golf course. Before 1918, DuPont had constructed a labor camp consisting of several dozen temporary barracks, a YMCA, mess halls, and other structures. This labor camp was built to provide employee housing during rapid expansion of the workforce to meet World War I production demand. The camp was not intended for long-term use. By 1940, little evidence of the labor camp remained – it had been demolished in the early 1920s because plant production had declined after World War I. This property had been purchased by The DuPont Powder Company before 1915, and was conveyed to The DuPont Chemical Company in 1915. In 1960, DuPont conveyed the land to the Sakima Country Club.

1919 Shipping Area-2

The 1919 Shipping Area-2 was identified on the 1919 layout map as a “Shipping Area” with narrow gauge rail lines connecting 21 structures believed to be smokeless powder bunkers. Based on the 1940 aerial photograph and the property transaction record, the structures on the 1919 map likely were proposed but never constructed. There is no record that this property was ever owned by DuPont. This area is currently mostly agricultural farmland with a residential development located along the northern edge.

17.3 Pathway Analysis

The pathway analysis was performed in accordance with the methodology described in Section 3.7.1. As described earlier in this section, based on the historical area review, aerial photograph evaluation, and review of historical information, no areas were identified for further evaluation in the Off-Site FA.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The chemical process database was not queried because no manufacturing processes occurred in this focus area.
- Buildings, Trenches, and Utilities Review: Building layer, trench, and utility maps were not reviewed because this area is located off-site and was not associated with historical manufacturing operations.
- Soil Data: Soil analytical data are not applicable for this focus area. No further discussion is necessary.
- Sediment Data: Sediment analytical data are not applicable for this focus area. No further discussion is necessary.
- Surface-Water Data: Surface water analytical data are not applicable for this focus area. No further discussion is necessary.
- Groundwater Data: Groundwater analytical data for this focus area are limited to the Ballfield area of Off-Site Property #1 (see Figure 17-3). Data for VOCs, SVOCs, pesticides, herbicides, metals, and TICs for the active B Aquifer wells are provided in Appendix D. These wells are monitored as part of the NJPDES-DGW Permit Perimeter Monitoring Program and are discussed in Section 2. Low concentrations of methylene chloride and PCE have been detected above GWIIA criteria and are not related to the site based on historical use.

17.4 Summary of Recommendations

Based on the pathway analysis, additional investigations are not required in the Off-Site FA.

18.0 FOCUS AREA – PHARMACEUTICALS

Evaluation of the Pharmaceuticals FA indicates that there are no areas of interest, and no further investigation is necessary. This conclusion is based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

Historically, the location of the Pharmaceuticals FA was a residential community known as Fenton’s Beach and was purchased by the DuPont Powder Company sometime before 1915. This area was associated with the Carneys Point Works for an unknown period of time and was identified on a 1919 layout map as a “Shipping Area.” It is likely that operations related to the Carneys Point Works ceased in 1919, and that the rail lines and storage bunkers were removed shortly thereafter. This area remained vacant until about 1942 when the Caer Building and the Salem Canal guardhouse were constructed, along with three parking lots to support the rapid workforce expansion during World War II. Up to 1970, the only activities in the area were parking and site security. In 1990, DuPont constructed a pharmaceutical R&D facility in this area. There is no history of any manufacturing activity in this FA. There is one SWMU located within the Pharmaceuticals FA – a section of SWMU 17 (the A Ditch), but this section of ditch was not used for process wastewater and concentrations of site-related constituents are not detected in downgradient monitoring wells.

Details of these reviews and evaluations are presented in the rest of this section.

18.1 Areas of Interest

The Pharmaceutical FA is located in the southeast corner of the Chambers Works manufacturing area (see Figure 18-1). This focus area is approximately 21 acres and is bounded by the Salem Canal to the south, Shinn Road to the west, a rail yard to the north, and the residential community of Deepwater Village to the east. Buildings currently operating in this focus area include the following:

- ❑ Caer Building (823): headquarters for the site security operation
- ❑ Salem Canal Road guard house
- ❑ Booster Pump House (1400): pumps potable water from the Salem Canal intake to the Cogeneration facility

The Pharmaceutical R&D unit consists of eight primary buildings and several supporting structures that currently are vacant. The Pharmaceutical operations were sold and the land was leased by DuPont in 2001. Subsequent owners have transferred and most recently discontinued operations.

There is one SWMU located within the Pharmaceuticals FA – a section of SWMU 17 (A Ditch) runs along Shinn Road from the Caer Building to the north. Based on the aerial photograph review, it is believed that the portion of the ditch on the border of the Pharmaceuticals FA did not actually exist. Additional evaluation of this pathway is not necessary based on the history of the area; there were no processes, only a parking lot. Based on the aerial photograph review, pathway analysis, process knowledge, and American Society for Testing and Materials (ASTM) ESAs conducted during property lease transactions in 2001, 2003, and 2006, no areas of interest were selected for further evaluation and no further action is recommended.

18.2 History

Historically, the location of the Pharmaceuticals FA was a residential community known as Fenton's Beach and was purchased by the DuPont Powder Company sometime before 1915. This area was associated with the Carneys Point Works for an unknown period of time and was identified on a 1919 layout map as a "Shipping Area." Structures shown on the map connected by narrow gauge rail lines were believed to be smokeless powder storage bunkers. The only other feature in the area was Salem Canal Road running along the southern edge of the area adjacent to the Salem Canal (see Figure 18-2). This was a public roadway until 1927, providing access to the Fenton's Beach community. In 1927, DuPont completed the purchase of the Fenton's Beach lots and consolidated them into the Deepwater Dye Works. At this time, Salem Canal Road became a private road as well as the primary southern entrance to the Dye Works.

By 1940, there was little evidence of the narrow-gauge rail lines and associated structures on the aerial photograph, indicating that these features were removed many years earlier. Based on available research, Carneys Point operations were scaled down rapidly after World War I (DuPont, 1978). It is likely that operations in this area related to the Carneys Point Works ceased in 1919, and that the rail lines and storage bunkers were removed shortly thereafter.

This area remained vacant until about 1942 when the Caer Building and the Salem Canal guardhouse were constructed. In addition, three parking lots were constructed in the area for additional employee parking to support the rapid expansion that occurred during World War II. These parking lots were located outside the perimeter security fence and were used by employees. Up to 1970, the only activities in the area were parking and site security.

In 1970, a production well [INT-106 (L04-R01CD)] was installed in the area as part of the IWS to recover and maintain groundwater containment. Water pumped from the well was conveyed via an underground pipeline to the on-site WWTP located to the north. This well operated until 1990 when it was abandoned prior to construction of the pharmaceutical research and development (R&D) buildings.

In 1990, DuPont constructed a pharmaceutical R&D facility consisting of eight primary buildings and several supporting structures. This facility, used to investigate pharmaceutical intermediates and perform pilot-scale testing, was operated by the DuPont Pharmaceuticals Division until 2001 when the division was sold to Bristol Myers Squibb (BMS). DuPont conducted a Phase I ESA prior to divestiture of the property in accordance with ASTM standards. BMS leased the facility from DuPont and continued operations until 2003. In 2003, BMS vacated the facility and transferred its operations to another site. In October 2003, Rhodia, Inc., leased the facility from DuPont to conduct pharmaceutical R&D. Rhodia conducted Phase I and II ESAs to document baseline environmental conditions prior to occupying the facility. The Rhodia lease of the facility ended in August 2006 when Rhodia vacated the facility. Currently, the facility is idle and is maintained by DuPont.

18.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. Based on the historical area review, aerial photograph evaluation, review of existing data from various media, review of historical investigations, and review of existing remedial documentation, no areas of the Pharmaceuticals FA warrant further action.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- Chemical Process Database: The chemical process database was not used for this area because there were no historical operations in the area. The only operations of significance in the area were related to the Pharmaceuticals R&D facility that was constructed in 1990. Process information for the Pharmaceuticals facility was evaluated in 2001 and again in 2003 to identify potential areas for environmental concern as part of the ASTM ESA process required for property transactions. These recent reports indicate no areas for additional investigation.
- Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area. A section of SWMU 17 (A Ditch) is located along the western edge of the area and formerly conveyed sanitary waste away from the Caer Building to the north. Sanitary waste from this building is currently conveyed to the on-site WWTP via overhead pipeline. There are currently two drainage swales at the eastern end of the area that convey stormwater to the Salem Canal. This area is currently managed under the SPCC. The drainage area was not retained as an area of interest based on the current management and historical understanding that no processes were located in the area.

  Figure 18-3 shows the trenches and outfall discharge locations.
- Soil Data: Soil analytical data for this focus area are not available.
- Sediment Data –Sediment analytical data for this focus area are not applicable
- Surface-Water Data: Surface-water analytical data for this focus area are not applicable.
- Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D for VOCs, SVOCs, pesticides, herbicides, metals, and TICs for the active B Aquifer wells and for the abandoned wells.

  In compliance with the NJPDES-DGW Permit No. NJ0083429, groundwater quality in site perimeter wells is monitored. The wells in this program in proximity to this focus area are shown in Figure 18.4. Monitoring wells L04-

M01B, M03-M01B, N04-M01B, and O05-M01B are monitored as part of the DGW program and indicate no impact from site operations.

Shallow groundwater (see Figure 18-4) in the Pharmaceuticals FA flows toward the interior of the site to the northwest.

18.4 Summary of Recommendations

Based on the pathway analysis, additional investigations are not required in the Pharmaceuticals FA.

19.0 FOCUS AREA – MISCELLANEOUS

Evaluation of the Miscellaneous FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

DuPont recommends sampling groundwater in the vicinity of the Manhattan Engineer District (MED)-related buildings and associated process wastewater ditches to assess groundwater quality and the potential presence of DNAPL. From 1943 to 1945, 30 MED-related buildings were in operation in the Miscellaneous FA, and nearby ditches probably were used to dispose of wastes. Buildings 886 and 1149 were converted from MED-related use to Monastral production. Nitrotoluene and nitrochlorobenzenes were related to the Monastral process, so possible impacts from this process should be discernable based on groundwater data.

DuPont recommends sampling groundwater downgradient of the railroad loading and unloading area south of Building 1060 where a section of SWMU 56A is located adjacent to the railroad tracks. This area was used from the mid-1950s to the present. The shallow groundwater sampling is recommended to assess whether this area has been impacted by historical site activities.

The full evaluation is presented in the rest of this section. Details about the recommended investigations, such as number and location of monitoring wells, sampling points, and sampling methodology, will be presented in subsequent work plans.

19.1 Areas of Interest

The Miscellaneous Focus Area (FA) is a 43-acre parcel in the southeastern section of the Chambers Works Complex. It is bounded by the SWMU 8 FA to the north, the Aramids and White Products FAs to the west, the Pharmaceuticals FA to the south, and the community of Deepwater Village to the east (see Figure 19-1).

A number of areas or features are pertinent to the history of the Miscellaneous FA, as shown in Figure 19-2. Ten of these areas have had investigations and/or remedial actions that have been completed. These areas are listed below and included only in the history section of this focus area:

- SWMU 33: Former Manhattan Project-Related Building Area
- SWMU 41-1: Drum Storage Area
- SWMU 41-2: Drum Storage Area
- SWMU 41-4: Drum Storage Area
- SWMU 39-1: Underground Storage Tanks (USTs)
- Garage Diesel Spill Area (Building 1201)

- SWMU 55-6: Fill Deposition Areas
- SWMU 55-7: Fill Deposition Areas
- SWMU 17: Process Water Ditch System (PWDS)
- SWMU 56A: Historical PWDS

The Garage Diesel Spill Area and SWMU 39-1 are being addressed together even though historical releases occurred at different times. More detailed descriptions of these SWMUs were submitted in January 2002 in the report titled *Chambers Works FACT Sheets* (DuPont, 2002).

The remaining areas are discussed further in Section 19.3 and are shown in Figure 19-3:

- MED-Related Buildings Area
- Monastral Buildings 886 and 1149, and Associated Rail Spur
- Consolidated Warehouse Building 1060, and Associated Loading/Unloading Area

19.2 History

Before 1940, this focus area was mainly undeveloped land with bunkers associated with the Carneys Point Works scattered throughout. (The Carneys Point FA is discussed in Section 20.) From 1943 through 1945, the Miscellaneous FA was one location where work under the Manhattan Project was conducted. Immediately following this use, the majority of buildings were either demolished or renovated for office or lab use. Available records indicate that two buildings, 886 and 1149, were used for the Monastral process from 1978 through 1998. More detail is provided in the following sections.

Currently, the Miscellaneous FA consists of the consolidated warehouse (Building 1060), plant medical, plant garage, and miscellaneous drum and trailer storage areas. No operational process areas are currently located within this focus area.

19.2.1 MED-Related Buildings and SWMU 33: Manhattan Project-Related Buildings

In 1942, DuPont entered into an agreement with the ACOE to become involved with the work under the Manhattan Project, so named because it was managed within the U.S. Army Manhattan Engineering District (MED). The ACOE had approached DuPont mainly because of its experience in safely manufacturing fluorinated compounds, which were the only class of compounds compatible with uranium hexafluoride. Not until the end of the war was it revealed that the site had participated in the nation’s atomic energy program.

Multiple locations at the site were associated with work under the Manhattan Project. One of these areas – designated as the East Area – is located in the Miscellaneous FA. Construction of the East Area began in 1943. The ACOE hired subcontractors to clear and grade the land, lay out the roads, and construct the process buildings and associated utilities. The East Area consisted of 30 buildings on 21 acres between the four blocks to the north of Broadway and three blocks to the south of Broadway (see Figure 19-2). DuPont employees under the supervision of the ACOE were in charge of the East Area production of fluorinated lubricants and solvents. In mid-year 1945, East Area operations began to ramp down and operations ceased by the end of the year.

In 1946, project activities were turned over to the Atomic Energy Commission. Most of the buildings were quickly dismantled in 1946. Also in 1946, some rubble and waste from the F Corral, another area associated with the Manhattan project, was buried along East Road in the East Burial Area. This area is located in the SWMU 8 FA just north of the Miscellaneous FA and is being addressed by FUSRAP. The current FUSRAP scope in this area involves only the uranium rubble and waste that was removed from the Fluoroproducts FA and buried in the East Burial Area. No activities associated with uranium are known to have occurred in the East Area.

DuPont purchased the buildings from the Atomic Energy Commission in 1949. One of the former East Area buildings (910) was used as a warehouse by the Ponsol Area to store crude colors and intermediates. Two other buildings were extensively remodeled for the Petroleum Laboratory facilities (P-2 and P-3). Other buildings where Manhattan Project work was conducted were razed. In 1952, the East Area Warehouse Building (910) was converted into a dryhouse facility.

19.2.2 Buildings 886 and 1149 and Associated Railroad Spur

Process records indicate that Buildings 886 and 1149 were used for Monastral production from 1978 to 1995. Building 886 was called Monastral Colors; Building 1149 was called the Nitrotoluene (NT)/Nitrochlorobenzene (NCB) Isomer Separation plus tank farm (see Figure 19-3). Waste streams either were incinerated or were discharged to the ditches (SWMU 17) and treated at the WWTP. A railroad spur is located to the south of these buildings (see Figure 19-3) and may have been used for loading and unloading of process chemicals.

In 1986, Building 886 was used to produce N-5297 (O-methoxycarbonyl benzyl sulfonamide) using o-methylbenzoic acid reacted in several steps with methyl alcohol, chlorine, sodium thiosulfate, and ammonia in ODCB to form the sulfonamide. This intermediate (N-5297) was used to produce a rice herbicide.

In addition, in 1985, Building 886 was used to produce dimethyl-5-sulfo-isophthalide (DRL-6), a finishing agent used to aid in the dye receptivity of Dacron® fiber. The process involved reacting isophthalic acid with sulfur trioxide and then with methanol.

Two wells have been sampled in the vicinity of these buildings. These data were reviewed and are discussed in Section 19.3.

19.2.3 Consolidated Warehouse Building 1060 and Associated Railroad Loading and Unloading Area

Building 1060 was constructed in the mid-1950s and was used for shipping and receiving (see Figure 19-3). Various finished products were stored here until shipped. In addition, raw materials were stored when received until they were dispersed to other plant locations. Building 1060 still serves as the warehouse for the site.

Products and materials were shipped and received via a railroad track that was located on the southern side of Building 1060. A ditch section (SWMU 56A) also runs along the south of Building 1060.

Further discussion of these areas is provided in Section 19.3.

19.2.4 SWMUs 41-1, 41-2, and 41-4: Drum Storage Areas

During a 1987 site analysis, SWMU 41-1 was identified by the EPA as a drum storage area that was used to store raw materials, finished products, and waste material associated with manufacturing processes at the site. This area operated from 1960 and is currently a 2.7-acre paved area (see Figure 19-2). The southern half of this area is still an active drum storage area and is included in the NJDEP DPCC plan for the site. As part of the Phase III RFI, no further action was proposed for SWMU 41-1.

During a 1987 site analysis, SWMU 41-2 was identified by the EPA as a drum storage area that was used to store raw materials, finished products, and waste material associated with manufacturing processes at the site. This area operated before 1970, and it is not known when storage ceased. SWMU 41-2 is 0.62 acres of asphalt-paved area that is currently used as a parking area with an office trailer. The location of SWMU 41-2 is shown in Figure 19-2. As part of the Phase III RFI, no further action was proposed for SWMU 41-2.

SWMU 41-4 was a drum storage area that was used to store raw materials, finished products, and waste material associated with manufacturing processes at the site. This area operated before 1970, and it is not known when storage ceased. SWMU 41-4 is 0.60 acres that is currently covered by a concrete pad (see Figure 19-2). In 2002, a deed restriction was recorded with Salem County. An NFA and Covenant Not to Sue were issued by the NJDEP for SWMU 41-4 on October 24, 2002; therefore, no additional work is proposed for SWMU 41-4.

19.2.5 SWMU 39-1: USTs and Garage Diesel Spill Area (Building 1201)

SWMU 39-1 consists of three underground storage tanks (USTs) that were installed in 1987. The SWMU currently exists and the tanks contain gasoline or diesel fuel. These tanks are fiberglass reinforced, noncorrosive plastic tanks, internally lined with epoxy, with double-walled secondary containment. Overflow protection, automatic level recording, and precision monitoring were also installed. In a letter dated December 2, 1993, the EPA agreed to no further action for this SWMU. The location of SWMU 39-1 is shown in Figure 19-2.

During work on the DPCC release control project on June 8, 2004, damage to an underground diesel fiberglass transfer line (from the UST to the dispensing pump) occurred during the removal of the old concrete and asphalt pad. While testing the repair to the damaged diesel fiberglass line, approximately two gallons of diesel fuel spilled onto the ground. The spilled diesel fuel was contained in the surrounding pea gravel. The impacted pea gravel was excavated and placed into 55-gallon drums for disposal. DuPont immediately notified the NJDEP Hotline and informed the NJDEP Case Manager.

During excavation activities, some contaminated soil was observed directly underneath the dispensing pump directly under the dispenser cabinet. It is believed that this contamination resulted from historical leaks where the underground feed line connects to the dispensing pump piping. The dispenser does not contain an integral spill pan. However, the underground storage tanks are tested weekly through the leak detection system and the underground pipes are pressure tested annually by an outside contractor.

On June 16, 2004, approximately 450 gallons of diesel fuel leaked onto the ground during integrity testing of the underground diesel fiberglass transfer line. The integrity testing was the first phase of the repair process for the original June 8, 2004, diesel fuel spill. The diesel line was being tested from the UST to the dispensing pump. The spilled diesel fuel was contained in pea gravel. The spilled fuel, impacted pea gravel, and in some cases sandy clay was excavated and placed into roll-off dumpsters for disposal. DuPont immediately notified the NJDEP Hotline and informed the NJDEP Case Manager. The root cause of the leak was determined to be related to the construction project – a reinforcing rod used to secure the concrete construction forms had punctured the fiberglass transfer line.

DuPont submitted the *Garage Diesel Spill Work Plan (SWMU 39-1)* to the EPA and NJDEP (DuPont, 2004). The NJDEP approved the work plan contingent upon DuPont addressing their comments in a letter dated July 23, 2004.

The remedial actions completed for the Garage Diesel Spill Area included the following:

- ❑ Excavation of the diesel spill area
- ❑ Excavation of Diesel Pump No. 2 dispensing area (western portion of the former pump island)
- ❑ Excavation of Diesel Pump No. 3 and Gasoline Pump No. 4 dispensing areas (eastern portion of the former pump island)
- ❑ Placement of the excavated material into roll-off dumpsters for off-site disposal
- ❑ Removal of approximately 99 cubic yards of soil

DuPont submitted a *Remedial Action Report for Chambers Work Garage Area (39-1)* (DuPont, 2005) and a response to comments letter dated May 23, 2005. Additional details and sampling results are provided in these documents.

Future work to address this SWMU and the Garage Diesel Spill Area will be conducted outside of the PAR process as directed by the NJDEP. A field investigation to be conducted will include installing seven temporary well points and two permanent monitoring wells. DuPont has recommended continued monitoring of N07-M01A and of the two newly installed monitoring wells for a minimum of four quarters. This work is expected to begin by December 2006.

19.2.6 SWMUs 55-6 and 55-7: Fill Deposition Areas

SWMU 55-6 is a 0.59-acre area where fill material from the site was placed. DuPont has no records of the origin of the fill placed in this SWMU. Based on the Phase II RFI boring logs, the fill material consists of gray silty sand. SWMU 55-6 is covered with asphalt and is located south of SWMU 8 as shown in Figure 19-2. As part of the Phase II RFI, two soil samples were collected from SWMU 55-6. All detected concentrations of were below RDCSCC, NRDCSCC, and IGW, therefore no further action was proposed for SWMU 55-6.

SWMU 55-7 is a 0.90-acre area where fill material from the site was placed. DuPont has no records of the origin of the fill placed in this SWMU. Based on the Phase II RFI boring logs, the fill material consists of red and brown silty sand and gray coarse sand. SWMU 55-7 is a grass-covered area located outside the plant perimeter fence as shown in Figure 19-2. As part of the Phase II RFI, two soil samples were collected from SWMU 55-7. All detected concentrations of were below RDCSCC, NRDCSCC, and IGW, therefore no further action was proposed for SWMU 55-7.

19.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Chapter 3. As described throughout this chapter, the following areas warrant a pathway analysis:

- ❑ MED-Related Buildings Area
- ❑ Monastral Buildings 886 and 1149, and Associated Rail Spur
- ❑ Consolidated Warehouse Building 1060, and Associated Loading/Unloading Area

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❑ Chemical Process Database: Chemical process data were available for two buildings in this focus area (Buildings 886 and 1149).
- ❑ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area.
- ❑ Soil Data: Soil analytical data for this focus area are provided in Appendix D. Boring locations area shown in Figures 19-4 and 19-5.
- ❑ Sediment Data: There are no associated sediment analytical data for this focus area.
- ❑ Surface-Water Data: There are no associated surface-water analytical data for this focus area.
- ❑ Groundwater Data: Groundwater analytical data for this focus area are provided in Appendix D. Well locations are shown in Figure 19-6. Groundwater flow, as shown in Figure 19-6, is generally to the northeast (toward the IWS pumping well).

Based on a review of available soil and groundwater data and process knowledge of what was used and disposed of in the Miscellaneous FA, 1, 2-dichlorobenzene is used to illustrate the contaminant distribution. The detection of other compounds in samples was also considered. These data tables are presented in Appendix D.

19.3.1 MED-Related Buildings, Monastral Buildings 886 and 1149, and Associated Railroad Spur

As stated previously, 30 MED-related buildings existed at one time in the Miscellaneous FA. As shown in Figure 19-2, ditches were located around the perimeter of the blocks where buildings were located and were potentially used to dispose of waste materials during their period of operation (1943 to 1945).

Buildings 886 and 1149 were converted from MED-related buildings to use for Monastral production. Trenches associated with these buildings are shown in Figure 19-6. In addition, Waste streams were either incinerated or discharged to the ditches (SWMU 17) and treated at the WWTP.

A review of soil sampling data was completed for this focus area. Data are available from the investigations for SWMUs 39-1, 41-1, 41-2, 55-6 and 55-7. Sixteen samples were collected within this focus area as shown in Figure 19-4. All soil concentrations were below NRDCSCC; only benzene was detected above IGW at one location, which is associated with the SWMU 39-1 release.

A review of groundwater sampling data also was completed for this focus area. Wells L07-M01B and L08-M01B are located downgradient of Buildings 886 and 1149. These wells were installed as part of the SWMU 8 investigation. In reviewing these locations, it is also noted that the wells were installed in areas of historical aboveground tank locations – former PNCB storage and a gasoline tank farm (P-4) (see Figure 19-6).

Based on the presence of constituents in groundwater related to the Monastral production, it is recommended that additional characterization of groundwater be completed. These locations would include both MED-related buildings and Monastral process buildings.

In addition, groundwater be sampling downgradient of the rail spur that was used for Monastral is also recommended to evaluate this feature as a potential source to groundwater.

19.3.2 Consolidated Warehouse Building 1060 and Associated Railroad Loading and Unloading Area

A railroad loading/unloading area is located on the southern side of Building 1060. In the same area, a section of SWMU 56A is also located adjacent to the railroad tracks. The area was used from the mid-1950s through to the present day. No soil data are available to characterize this area. Therefore, soil and shallow groundwater sample collection is proposed to characterize this area.

19.4 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Miscellaneous FA:

- ❑ Collect groundwater samples in the vicinity of the rail spur to evaluate the potential effects on groundwater quality.
- ❑ Collect groundwater samples in the vicinity of the process wastewater ditches and process building trenches in the Monastral production area and former MED buildings to assess groundwater quality and potential presence of DNAPL.
- ❑ Collect groundwater samples downgradient of the former railroad loading/unloading area to evaluate the potential effects on groundwater quality.

Groundwater samples may be collected from wells that are currently not used for sampling purposes, where present, or by installing additional monitoring wells, for example. Details about the recommended investigations, such as the number and location of monitoring wells, sampling locations, and sampling methodologies, will be presented in subsequent work plans.

These investigation areas are shown in Figure 19-7.

20.0 FOCUS AREA – CARNEYS POINT

Evaluation of the Carneys Point FA indicates that further investigation of specific areas is warranted. The recommended investigations are based on the evaluation of historical process data, aerial photographs, site maps, analytical results of soil, sediment, and groundwater sampling, and on a pathway analysis. The review and analyses were conducted consistent with applicable regulations and guidelines.

In September 2006, DuPont submitted a Baseline Ecological Evaluation for the site that identified areas in the Carneys Point FA for further evaluation, including SWMUs 42, 45-2, 45-9, 52, 60, and 61 as well as several surface-water bodies and portions of Bouttown Creek. (DuPont, 2006) Investigation of these areas will be described in the Ecological Investigation Work Plan that will be submitted in early 2007.

DuPont recommends review of the metals occurrence in the Carneys Point FA after completing the ecological investigation and the Phase IV RFI metals mobility study. Preliminary assessment of the FA indicate that metal detections in groundwater, sediment, soil, and surface water seem to be ubiquitous within the various SWMUs throughout this FA. Further evaluation of the vertical groundwater transport for mobile metals is currently underway in the SWMU 45-2 area as part of the Phase IV RFI Supplemental Work Plan.

Two areas were identified during the pathway analysis as requiring additional investigation: 1) a white discharge from the nitrocellulose manufacturing area along the western bank of Bouttown Creek and the Bouttown Tidal Flat, and 2) the acid release fume ponds in northern Carneys Point. To address these areas, DuPont recommended sampling the soil/sediment and surface water in two ponds, Bouttown Creek, and the Bouttown tidal flat to determine if there were any constituents of potential ecological concern (COPECs) caused by the manufacturing operations at Carneys Point Powder Works Plant 1.

In soil samples, SVOCs detected throughout Carneys Point include benzo(a)anthracene, benzo(b)fluoranthene, benzo(a)pyrene, benzo(k)fluoranthene, and dibenz(a,h)anthracene. Metals were the main analytes that exceeded criteria in soil at Carneys Point.

Fewer than a quarter of the groundwater samples from abandoned A, B, and C Aquifer wells had detections exceeding criteria. Elevated levels of 1,1,2,2 tetrachloroethane, 1,2 dichloroethane, benzene, methylene chloride, tetrachloroethylene, trichloroethylene, bis(2-ethylhexyl)phthalate, and N-nitrosodimethylamine were detected in at least one sample.

From the active C Aquifer wells (which include B Aquifer groundwater where the BC clay layer is missing) roughly half the samples had detections exceeding criteria: analytes detected at elevated levels in at least one sample included 1,1,2,2-tetrachloroethane, 1.1.2-trichloroethane, 1,1-DCE, 1,2-DCA, 1,4-DCB, acrolein, acrylonitrile, benzene, chlorobenzene, methylene chloride, PCE, TCE, 1,2,4-TCB, 2,4-dinitrophenol, bis 2-ethylhexylphthalate, N-nitrosodimethylamine, and dieldrin.

Although no SWMUs warrant a pathway analysis for the Carneys Point FA, the entire focus area was subjected to further evaluation to confirm the findings of the previously submitted BEE. Details of these reviews and evaluations are presented in the rest of this section.

20.1 Areas of Interest

The Carneys Point FA (also known as Carneys Point Works and Plant 1) is approximately 758 acres located in the northernmost section of the Chambers Works Complex and borders the Delaware River to the west and Helms Cove to the north. Carneys Point is bordered to the east by Shell Road (Route 130) and to the south by the WWTP and Dyes FAs (see Figure 20-1).

Two named waterways cross the Carneys Point FA: Bouttown Creek in the northern section and Henby Creek at the southern section, just north of the current WWTP (see Figure 20-2). Bouttown Creek discharged to the north directly to the Delaware River via a sluice gate prior to 1974, and currently discharges into Henby Creek to the south. Henby Creek enters the Carneys Point FA at the east and discharges to the west into the Delaware River via a sluice gate.

The SWMUs listed below are located within the Carneys Point FA and have been previously investigated and/or remediated; therefore, these SWMUs are not included in the pathway analysis of this focus area. However, a pathway analysis was performed for the focus area as a whole using available SWMU data to confirm the findings of the previously submitted BEE.

- SWMU 13: Secure C Landfill
- SWMU 19: Nitrocellulose Disposal Area
- SWMU 37: Disposal Area
- SWMU 42: Henby Creek
- SWMUs 44 and 53: Surface Water Impoundment and Water Treatment Facility
- SWMUs 45-1 through 45-8: Manufacturing Areas
- SWMU 45-9: Former Process Drainage System
- SWMU 46: Dredged Spoils Area
- SWMU 47: Areas of Fill Deposition
- SWMUs 48-1 through 48-7: Storage/Cleaning Areas
- SWMU 49: Dewatering Pad
- SWMU 52: Debris Disposal Area
- SWMU 54: Solvent Recovery Units (Plant 2)
- SWMU 60: Drum Disposal Area
- SWMU 61: Disposal Area II

These SWMUs are shown in Figure 20-2. More complete descriptions of these SWMUs were submitted in January 2002, in the report titled *Chambers Works FACT Sheets* (DuPont, 2002). See Figure 20-3 for areas of interest.

20.2 History

DuPont purchased the Thomas Carney farm from the Norton family in July 1891 to manufacture explosives. A considerable portion of the ground was marshland, which provided natural firebreaks in the event of an explosion. The plant began operations by May 1892. All of the major manufacturing areas and support functions were conducted on the narrow peninsula projecting northward, surrounded on one side by the Delaware River and on the other by Bouttown Creek and the marsh. Storage and shipping areas were noted to be on the "mainland" beyond the point. By the end of 1892, 100,000 pounds of nitrocellulose were delivered to the U.S. Navy.

Between 1902 and 1910, several new powder lines were moved to Carneys Point from their original locations. Between 1906 and 1912, the Carneys Point Plant was almost completely re-built. At this time, DuPont owned 100% of the non-government plants capable of producing military powder and Carneys Point was the largest. Beginning in October 1914, DuPont constructed new plants and tripled production capacity in order to supply gunpowder for the Allied troops in WWI. The existing production line (Plant 1) was considered the "A" line, and two more lines ("B" and "C") would be constructed starting in late October 1914. Production lines "B" (Plant 2) and "C" (Plant 3) were in full operation by the beginning of 1915. The production capacity of Plants 1, 2, and 3 was approximately 100 million pounds of smokeless powder per year. Normal daily output of the three plants exceeded two-thirds of a million pounds per day for extensive periods during WWI.

Another unit, sometimes referred to as Plant 4, was constructed at Deepwater Point. This plant was established by the Explosives Department to manufacture picric acid by the nitration of phenol and production of dimethylaniline (DMA) for conversion to tetryl. This plant was eventually known as the "High Explosive Plant" for the Dye Works and later the "Kinetic" and Freon plants (see Section 6). The first picric acid was produced in 1915. In this same year, the Saltpeter Plant was built near the waterfront about midway between the High Explosive Plant and Salem Canal mouth. This plant was built to refine crude nitrate by removing impurities and providing high-quality sodium nitrate to the powder plants.

In 1919, military orders for explosives were canceled and the Powder Works slowly contracted as the Dye Works expanded. Plant 1 operated continuously from WWI through WWII and on until 1977, making nitrocellulose and smokeless gunpowder and following the same general procedures that had been in operation since WWI. Production increased during the WWII years (1938 to 1945). Some spin-offs of the nitrocellulose production included nitrate film (celluloid), carboxy methyl cellulose (CMC), lacquer, cellulose acetate, and rayon.

Based on an interview with a current Chambers Works employee who worked at Plant 1, three manufacturing operations existed at the Carneys Point Powder Plant: smokeless powder, nitrocellulose, and CMC. By 1976, only two manufacturing operations remained: primary powder and nitrocellulose. Carneys Point ceased the production and packaging of finished powder in 1969, after a "Finishing Area" explosion. A smokeless powder area mix house explosion in the spring of 1978 hastened the downturn of the Carneys Point Plant 1, and smokeless powder production stopped immediately.

A summary of the chemical processes used at Carneys Point from the 1890s through the closure of Plant 1 was developed from various DuPont sources and former employee interviews is provided in Appendix T. Chemical processes in Carneys Point Works were significantly different from the Chambers Works manufacturing area to the south. The Carneys Point Works primarily used cellulose (cotton or wood fibers), alcohols, and acids as part of the manufacturing process.

Production at the rest of the site probably stopped in 1978. Decommissioning of Plant 1 was underway in 1978 and was completed around 1979. During this time, most process records associated with the Carneys Points works was lost or destroyed.

Most of the Carneys Point FA is currently idle. The only current operation in the area is the RCRA permitted Secure C Landfill (SWMU 13). To the north of the landfill is a wildlife habitat area containing some concrete foundations, railroad tracks, and roads associated with past operations.

20.2.1 40-Acre Parcel

Three phases of an Environmental Site Assessment (ESA) were completed on a 40-acre parcel of land within the former Carneys Point Works between 2000 and 2004 (see Figure 20-2). The ESA was completed to determine if the area was impacted by recognized environmental conditions (RECs) and, if so, the potential impacts for leasing the property. The identified RECs included the following:

- A fuel pump island and UST formerly located adjacent to the southeast corner of the site.
- A pole-mounted electrical transformer, disposal field, and silo identified on historical plant maps adjacent to the southeast corner of the site near a former guardhouse.
- Two SWMUs (48-6 and 48-7) located along the western boundary of the site.

In response to NJDEP and EPA comments, soil and groundwater samples were collected and groundwater elevation measurements were obtained to confirm groundwater flow direction. Based on the findings of the assessment, the following conclusions were drawn:

- Several inorganic constituents were present in groundwater above the GWIIA. These results were consistent with average background groundwater quality results in this portion of the site.
- Groundwater flow direction on-site is toward the interior of the site and groundwater quality is monitored on a quarterly basis for the entire site as part of NJPDES-DGW permit NJ0083429. Therefore, constituents detected in site groundwater do not have a significant potential for off-site migration.

- All soil sample analytical results were below RDCSCC. Also, nitrocellulose was not observed on-site based on visual observation. (Note: there is no analytical method for nitrocellulose determination)
- Based on the samples collected during this ESA Phase III, the RECs identified in the ESA Phase I were determined to have not caused significant impact to the site.
- There were no environmental conditions observed that would preclude leasing the site.

Based on the history of the area and sample analytical results as described above, no further action is recommended for this area.

20.2.2 SWMU 13 (Secure Landfill C)

DuPont has operated the Secure C Landfill at the Chambers Works Complex within the former Carneys Point Plant 1 area since 1975. The landfill covers approximately 29 acres and currently consists of six areas (formerly called “cells”). Area 1 of the Secure C Landfill was closed in 1979 and is under RCRA corrective action. Areas 2, 3, 4, 5A, and 5B are currently active and are permitted as a RCRA Subtitle C secure landfill. The entire landfill is lined and Areas 2, 3, 4, 5A, and 5B are double-lined, with leak-detection systems between the liners to monitor for seepage through the upper liner. A leachate collection system for removing accumulated leachate from the liners is provided and monitored in all five areas. Area 5B of the Secure C Landfill began receiving waste in April 2005 and was added to the Leachate Collection System Monitoring Program. Future areas 5C, 6, and 7 will be added as additional landfill space is required. The Secure C Landfill currently accepts secondary sludge from the WWTP that is characterized as a RCRA listed waste (F039).

The Corrective Action Groundwater Recovery Program for the Secure C Landfill was designed and implemented to control groundwater flow and recover impacted groundwater associated with Area 1 of the Secure C Landfill. Wells Q20-M02B and R20-M02B are used as groundwater recovery wells. Captured groundwater is pumped to Sumps 1 and 2 of the Secure C Landfill leachate collection system. It is then transported to the WWTP for treatment. Corrective action wells Q20-M02B and R20-M02B are normally operational, but may have some interruptions at times when the wells are shut down due to extensive rain. If a significant amount of rain occurs, the wells are turned off so that water can be pumped off the active landfill.

DuPont Secure Environmental Treatment (SET) is currently evaluating a project to improve the reliability of the leachate collection system to better manage stormwater and the addition of future landfill cells. If feasible, this improvement project should eliminate any downtime for the pumping wells due to leachate collection system capacity. DuPont anticipates the evaluation to begin by the fourth quarter of 2006.

Based on groundwater elevation contour maps, groundwater containment for Secure C Landfill is effective. The Corrective Action Program wells capture groundwater from Area 1, Area 2, and portions of Areas 3, 4, 5A, and 5B, and a capture zone is evident. The corrective action monitoring program for Area 1 of the Secure C Landfill monitors groundwater quality in the following five wells in compliance with NJPDES-DGW

Permit No. NJ0083429: P21-M01B, P21-M03B, Q20-M02B (pumping well), Q21-M01B, R20-M02B (pumping well). All five wells and the background wells S24-M01B and T22-M01B are monitored semiannually for Secure C Landfill Corrective Action (CLF-CA) target analytes. Cell 1 of SWMU 13 has received a NFA and Covenant Not to Sue letter from NJDEP dated October 24, 2002.

Because the Secure C Landfill is currently operating under a NJDEP permit and Cell 1 has been closed and currently undergoing RCRA closure monitoring, no further evaluation of this area as part of this PAR is necessary. No additional investigation is recommended.

20.2.3 SWMU 19 (Nitrocellulose Disposal Area)

SWMU 19 is 2.4 acres and was used to dispose of off-quality nitrocellulose from Carneys Point. The disposal areas are located southeast of River Road and northeast of Boundary Road. Disposal involved dumping wastes into water-filled pits and covering them with soil, a method used to prevent accidental explosions.

In the early 1980s, SWMU closure began. The areas were drained and the waste materials were excavated and ignited with a portable oil burner. Approximately 2,600 cubic yards of soil was excavated and treated in a rotary kiln. The treated materials were laboratory tested for ignitability and then backfilled to the excavated areas. Delineation samples were collected and tested for the presence of nitrocellulose by ignitability testing with a hand-held propane torch. Results indicated that incineration of nitrocellulose was completed. In November 1987, a final closure certificate was granted by the NJDEP Division of Hazardous Waste Management to DuPont for SWMU 19. In December 1990, DuPont submitted the certificate of closure from NJDEP to the EPA, with a recommendation of no further action. In response to the request, EPA issued a letter dated November 1990 for additional soil samples to be collected beneath the processed soil. DuPont collected the soil samples requested by EPA. Findings from the sampling indicated that SWMU 19 was not used for disposal of any wastes other than nitrocellulose. DuPont requested no further action for SWMU 19.

Part of SWMU 19 was included in the wetlands mitigation for SWMU 43. To compensate for the unavoidable losses of wetlands and aquatic habitat during the ISM actions at SWMU 43, DuPont created emergent freshwater wetlands along Henby Creek (DuPont, 2001). The 2-acre area was lowered so that the ground surface elevations would conform to those in the adjacent wetland area.

Because this SWMU has been remediated and is being used as a wetlands mitigation area, no further action remains the recommendation for this SWMU; no evaluation is necessary as part of this PAR.

20.2.4 SWMU 37 (Disposal Area)

SWMU 37 (trade waste pit) was a 20-foot-diameter basin used as a temporary accumulation area for trade wastes associated with nitrocellulose and smokeless gunpowder manufacturing processes. Off-specification products were mixed with water in the manufacturing areas, and the slurry was pumped to SWMU 37 for settling of solids. Liquid runoff from this area entered Bouttown Creek via a spillway. SWMU 37 was occasionally cleaned out and the material was deposited in the nitrocellulose disposal area (SWMU 19).

SWMU 37 was investigated as part of the Phase I RFI. Based on the results, it was concluded that concentrations present would not impact groundwater quality. No further action was proposed for SWMU 37. Therefore, no further investigation of SWMU 37 is recommended; however, the area of Bouttown Creek that received discharges from SWMU 37 will be included in the ecological investigation..

20.2.5 SWMU 42 (Henby Creek)

SWMU 42 is a creek that originates off-site and traverses southeast to northwest, south of the former Carneys Point Works. Henby Creek represents the primary surface water drainage pathway from Carneys Point. Bouttown Creek, the other surface water body on Carneys Point, also originates off-site. Formerly, Bouttown Creek discharged directly into the Delaware River; however, the original point of discharge has been cut off and filled and, therefore, no longer exists. Currently, Bouttown Creek discharges into Henby Creek.

Sediment and surface water samples were collected at this SWMU during Phases I through IV of the RFI. Results indicated detections of metals and PAHs. This SWMU is being addressed as part of the ecological investigation as recommended in the BEE. As a result, no additional evaluation is necessary as part of this PAR.

20.2.6 SWMUs 44 (Surface Water Impoundment) and 53 (Water Treatment Facility)

SWMU 44 consisted of three impoundments: a domestic water pond, a settling basin, and a fire water pond. Water was pumped from water supply wells located within the Carneys Point facility and as far as three miles to the east of the operating area. The water was treated before being pumped to the domestic water pond. The treatment consisted of adding lime and chlorine gas to reduce pH and kill bacteria. The water was then pumped to the eastern section of the domestic water pond to allow iron to settle out. After settling had occurred, the water was pumped to the western section of the domestic water pond for future use in the powerhouse boilers for steam generation or was pumped through sand filters and into a concrete water reservoir (SWMU 53). The settling basin, located east of the domestic water pond, served as a temporary pond that received dredged settled iron particulates from the domestic water pond. The fire water pond was used as a reservoir to store fire-fighting water for the Carneys Point Works. Excess water coming into the water treatment plant from the off-site water supply wells was diverted to the fire water pond. The water reservoir and the water treatment plant were demolished and removed between 1978 and 1980.

DuPont requested that the areas identified as SWMUs 44 and 53 be removed from its HSWA permit renewal application that was submitted May 7, 1993. In a December 6, 1993, letter to DuPont, the EPA requested further documentation (e.g., personnel interviews, historical information) to support the removal request. The information summarized above was provided in the Phase I RFI report submitted to the EPA on May 26, 1995.

As a result, no further evaluation of SWMUs 44 and 53 is necessary as part of this PAR.

20.2.7 SWMUs 45-1 and 45-3 through 45-8 (Manufacturing Areas)

SWMU 45 is composed of nine areas, eight of which involved nitrocellulose and other explosives manufacturing. SWMUs 45-1, 45-3, 45-4, and 45-5 were investigated in 1990 as part of the Phase III RFI. Results are summarized as follows:

- SWMU 45-1 results indicated some detections of SVOCs with no screening criteria available, and benzo(a)pyrene and arsenic above NRDCSCC.
- SWMU 45-3 results indicated some detections of SVOCs (no screening criteria available) and no exceedances of NRDCSCC.
- SWMU 45-4 results indicated that all constituent concentrations were below NRDCSCC.
- SWMU 45-5 results indicated SVOC constituent concentrations with no screening criteria available were detected, and arsenic above NRDCSCC.
- SWMU 45-6 was investigated as part of the Phase III RFI. Metals were detected in the soil at concentrations below NRDCSCC. A groundwater sample was collected from the SWMU and several SVOCs and metals were detected at concentrations greater than GWIIA .
- SWMU 45-7 was also investigated as part of the Phase III RFI. One soil sample was collected from SWMU 45-7 with SVOCs and metals detected below NRDCSCC.
- SWMU 45-8 was investigated on several occasions. Results indicated some detections of SVOCs with no screening criteria available or a few constituents at or slightly above NRDCSCC.

Because only a limited number of SVOCs have been detected at low concentrations in soil and groundwater, no additional evaluation of these SWMUs is necessary as part of this PAR. Metal mobility from recharge to groundwater for the northern Carneys Point area is currently under investigation as part of the Phase IV RFI Supplemental Work Plan. Metals in soil and groundwater were retained for further evaluation in this PAR.

20.2.8 SWMU 45-2 (Manufacturing Area 2)

SWMU 45-2 is located at the northernmost extent of the Carneys Point Works. It consists of several large concrete foundations that were part of the former Carneys Point nitrocellulose manufacturing operations. The SWMU includes the storage tank area of the former operations. The tanks were used for storage of nitric and sulfuric acids that were used in the adjacent manufacturing operations. A nitrating house was located about 50 feet to the southwest of the acid tanks. The building was use to mix raw cellulose fiber with acids as the first step of the manufacturing process. Two other buildings were located about 200 feet northwest of the nitrating building. These buildings were used as an unloading platform and warehouse/grinding house for the raw material. Most of the building foundations were removed during plant closure. The only remaining foundation is the elevated concrete walkway that connected the unloading house to the grinding house and the railroad spurs.

DuPont previously investigated SWMU 45-2 on five separate occasions. The initial SWMU 45-2 designation applied to the tank foundations and the nitrating house. Investigation results were submitted to the EPA and NJDEP in the Phase I and II RFI. Metals were identified as the primary constituents of potential concern. Extensive sampling was performed during Phase II to delineate the metals; delineation was attempted during several phases, with a total of 114 samples collected at 70 locations. Arsenic, copper, lead, and zinc, were detected in soil at concentrations exceeding NRDCSCC. The results of the sampling did not achieve complete horizontal and vertical delineation. The metals were horizontally delineated in soil in the eastern portion of the SWMU.

As part of the Phase II RFI, the existing data (surface and subsurface soil, SPLP metal data, boring logs, and site history) were re-evaluated to determine if future actions were warranted to be protective of human health and the environment. There was no obvious pattern to the metal concentrations across SWMU 45-2 or associated with the railroad lines. The presence of uniform elevated concentrations with depth, along with a similar concentration pattern detected beneath the historical buildings, may indicate that fill material was brought onto the site prior to the construction of the buildings. Historical evidence indicates that many building constructed for the original plant were removed and replaced prior to 1940 as production shifted from smokeless powder to nitrocellulose.

SPLP data were used as an indicator for potential leaching of soil by natural precipitation. Review of results from the initial 22 borings indicated that lead and arsenic SPLP concentrations exceeded the GWIIA. Samples outside of the NRDCSCC delineation were considered as a potential concern for groundwater. Based on the review of the data, the objective of the SWMU 45-2 Phase IV RFI investigation was to determine whether metal concentrations in soil have impacted groundwater and to determine groundwater flow direction within SWMU 45-2. Results of the Phase IV RFI study, as based on the evaluation of potentiometric contour maps and transducer data, indicated that shallow groundwater within SWMU 45-2 is influenced by recharge (precipitation events) rather than tidal interactions with the Delaware River. Recharge may cause a downward gradient from the shallow zone to the B Aquifer or toward surface water bodies in the interior of the SWMU, with the exception of the northern part of the area (which is toward the Delaware River).

The Phase IV sampling objective was further refined in the Phase IV Supplemental Work Plan so as to evaluate the potential migration of metals from soil to groundwater by installing water table wells and some B Aquifer wells. The Phase IV Supplemental Work Plan is currently being completed. DuPont expects to submit a report of findings for this work in 2007. This SWMU will also be evaluated as part of the ecological investigation.

20.2.9 SWMU 45-9 (Former Process Drainage System)

SWMU 45-9 conveyed liquid wastes from the former Carneys Point manufacturing areas via earthen ditches and pipelines to SWMU 37 or to Bouttown Creek. The drainage system was used from 1941 to 1979. In 1992 and 1993, about 12,000 linear feet of the process drainage system (mainly terra cotta and steel pipes) was removed from the proposed D Landfill Area. Approximately 71,000 pounds of nitrocellulose and other waste explosives were removed from this area. The remaining portion of SWMU 45-9 process drainage (that was not removed as part of the Landfill D activities) measures about 15,000 linear feet.

In 1999, DuPont capped the open-ended, exposed SWMU 45-9 pipes to prevent potential discharge from the pipes into the earthen ditches and Bouttown Creek. In March 2000, DuPont implemented a semi-annual surface water monitoring program at SWMU 45-9. Surface water sampling occurs at locations where the buried pipes and earthen ditches discharge into Bouttown Creek. Currently, 15,000 linear feet of piping remains in the ground and 1,000 feet of ditches are present in the area.

As part of the Phase II RFI, four main pipes discharging into the ditches were investigated. Material in the pipes and soil in the ditches were both sampled. In the pipes, no VOCs were detected above NRDCSCC and only one SVOC was detected above NRDCSCC. Four metals – antimony, arsenic, lead, and mercury – were detected in SPLP analysis at concentrations greater than IGW criteria in samples taken from the pipes. Arsenic, beryllium, copper, and lead were detected in the earthen ditches at concentrations above NRDCSCC. No VOCs, SVOCs or nitroaromatic/nitroamine compounds were detected in the earthen ditches at levels above NRDCSCC. Lead was the only metal detected in the earthen ditch SPLP samples above the IGW criteria. SWMU 45-9 will be evaluated as part of the ecological investigation.

Because of the limited presence in soil of VOCs and SVOCs in SWMU 45-9, no further evaluation is necessary as part of this PAR. Metals in soil and groundwater were retained for further evaluation in this PAR.

20.2.10 SWMU 46 (Dredging Spoils Area)

SWMU 46 was a 35-acre diked area that received dredged spoils from the Delaware River. Every one to two years approximately 80,000 cubic yards of river sediment was dredged from the wharf area. The dredging was authorized by a NJDEP permit and required sampling of the dredged material. The river sediment is known to contain heavy metals and organic compounds. In a 1987 analysis of the river sediments, magnesium, arsenic, cadmium, and lead were detected above screening levels. In 1989, five samples of the dredged spoils were collected from SWMU 46. Results indicated no detections of pesticides/PCBs, total cyanide, or organic lead. All organic and inorganic concentrations detected in the soil samples were below NRDCSCC. DuPont requested a conditional NFA with deed restriction for SWMU 46. Based on these results, no further evaluation is necessary as part of this PAR and no further investigation is recommended.

20.2.11 SWMU 47 (Areas of Fill Deposition)

SWMU 47 is 4.5 acres and extends about 850 feet along the northeastern shore of Bouttown Creek. Dredged sediment from Bouttown Creek was deposited in this SWMU. Periodic dredging of Bouttown Creek was necessary for area drainage.

SWMU 47 was investigated, and only arsenic was detected above the NRDCSCC in the dredged materials. A deed notice and Covenant Not to Sue was issued by NJDEP on October 24, 2002 for SWMU 47. Based on these results, no further evaluation is necessary as part of this PAR.

20.2.12 SWMUs 48-1, 48-3, 48-5 - 48-7 (Storage/Cleaning Areas)

Drums of nitrocellulose and related manufacturing materials were cleaned and/or stored in SWMUs 48-1, 48-3, and 48-5 through 48-7. Currently, most of these areas are overgrown with trees and/or underbrush. Portions of SWMUs 48-6 and 48-7 are covered with asphalt. SWMU 48-5 is currently a grassy meadow. SWMUs 48-1, 48-3, 48-5, 48-6, and 48-7 were investigated as part of the Phase III RFI and the results are summarized as follows:

- SWMUs 48-1: One soil and one groundwater sample were collected during the Phase III RFI. Arsenic was the only constituent in soil that exceeded NRDCSCC. Metals were the only constituents in groundwater that exceeded GWIIA.
- SWMU 48-3: One soil and groundwater sample were collected during the Phase III RFI. No constituents were detected in soil above the NRDCSCC. Metals were the only constituents detected in groundwater above the GWIIA.
- SWMU 48-5: One soil and one groundwater sample were collected during the Phase III RFI. No constituents were detected in soil above the NRDCSCC. Metals were the only constituents detected in groundwater above the GWIIA.
- SWMU 48-6: One soil and one groundwater sample were collected during the Phase III RFI. No constituents were detected in soil above the NRDCSCC. Metals were the only constituents detected in groundwater above the GWIIA.
- SWMU 48-7: One soil and one groundwater sample were collected during the Phase III RFI. No constituents were detected in soil above the NRDCSCC. Metals were the only constituents detected in groundwater above the GWIIA.

These SWMUs were evaluated in the BEE previously submitted to the NJDEP (DuPont, 2006). Results of the BEE evaluation indicate that no COPECs were identified. Overall metal issues in soil and groundwater were retained for further evaluation in this PAR.

20.2.13 SWMUs 48-2 and 48-4 (Storage/Cleaning Areas)

SWMUs 48-2 and 48-4 are two of seven areas in which drums of nitrocellulose and related materials were cleaned and/or stored. These SWMUs were investigated in 1990. SWMU 48-2 results indicated that lead and some VOCs exceeded the NRDCSCC. Some SVOCs were detected, but did not have applicable criteria. SWMU 48-4 results indicated that lead and mercury concentrations exceeded the NRDCSCC. Additional investigations were conducted to delineate the lead and mercury in soil. In 1992, an exposure assessment was conducted for SWMU 48-4, and no short-term exposure risk to the health of on-site workers was present. In a letter dated December 2, 1993, the EPA agreed to NFA for SWMUs 48-2 and 48-4. Based on this determination, no further action remains the recommendation for these SWMUs.

20.2.14 SWMU 49 (Dewatering Pad)

SWMU 49 was a dewatering pad less than an acre and was used to remove excess liquids from sludge and excavated materials before disposal into the C Landfill. The pad is covered in asphalt with a 4-inch-high asphalt berm. The pad is sloped to a drain that discharges any overflow to the leachate collection system.

Soil samples were collected from this SWMU. All constituent concentrations were below the NRDCSCC, except one sample contained elevated levels of base neutrals and lead. A 10-by-10-foot area around this sample location was excavated to a depth of 3 feet. Post-excavation samples were collected and no detections were above criteria. In a letter dated December 2, 1993, the EPA agreed to NFA for soil. Based on this determination, no further action remains the recommendation for this SWMU.

20.2.15 SWMU 52 (Debris Disposal Area)

SWMU 52, a former disposal and burning ground area, is located along the shoreline of the Delaware River in the Carneys Point FA. Material disposed at SWMU 52 from the 1920s until the late 1950s included various wastes from the Carneys Point Powder Works including debris, trash, and off-specification nitrocellulose.

Information and data collected from 1994 through 2005 delineated the horizontal and vertical limits of the area of concern in media, including native soil, fill material, agglomerated material, sediment, surface water, and groundwater. A chronology of previous investigations (and subsequent EPA and NJDEP comments) is listed below. Detailed descriptions of previous SWMU 52 investigations and detailed summaries are provided in the *SWMU 52 ISM Selection Report* (DuPont, 2004) and subsequent addenda (June 2005 and November 2005).

The Phase I RFI was implemented to characterize material along the shoreline, and was completed on May 26, 1995. SWMU 52 was reported in the *Addendum to the Phase I RFI Report: SWMU 52.* Activities included sampling soil and agglomerated material, reactivity testing, and implementation of an ISM.

In December 1994 and January 1995, DuPont implemented an ISM for SWMU 52 including installation of a fence at the high water line (SWMU boundary) to eliminate potential trespassing and potential contact with nitrocellulose and other site-related constituents (DuPont, 1998). In addition, sandbags were placed in the intertidal zone to reduce shoreline erosion during high tide. Subsequent wave action and erosion damaged the fence and sandbags.

DuPont completed the Phase II RFI in 1997 and submitted the Phase II RCRA Facilities Investigation Report (DuPont, 1998). The Phase II RFI activities at SWMU 52 included test pits, sampling of soil, agglomerated materials, and sediment, and reactivity testing.

Based on the results of the Phase I and II RFI, DuPont implemented a SWMU 52 investigation to evaluate whether site-related constituents presented a potential concern for human health and the environment. A conceptual site model refinement and characterization sampling work plan was submitted to the NJDEP on April 28, 2000. In October 2000, DuPont implemented the SWMU 52 work plan, which included collecting further soil data to refine the existing conceptual site model. Results were reported in a *SWMU 52 Investigation Report* dated January 28, 2002. In this report, DuPont concluded that the agglomerated material and metal debris are the likely source of metals at SWMU 52, especially via erosion and weathering of the agglomerated material.

EPA commented on the *SWMU 52 Investigation Report* in a letter dated Sept. 5, 2002. DuPont proposed to further investigate further the A zone and B Aquifer, and to delineate the impacted sediment within SWMU 52 as part of the remedial action design.

DuPont completed the supplemental investigation in the second quarter of 2003. In July 2004, DuPont presented a comprehensive SWMU 52 remedial measure selection report that summarized previous report findings from 1995 through 2003 and reported on results of the 2003 remedial investigation in the *SWMU 52 Remedial Action Selection Report* (RASR). By mutual agreement with the NJDEP, the selected remedial measure at SWMU 52 is an ISM.

DuPont completed an additional pre-design investigation in August and October 2004, and presented results in June 2005 in a report titled *Addendum No. 1 to SWMU 52 ISM Selection Report.* The report summarized additional upland and agglomerated material soil sample locations for design and waste-screening purposes, and expanded the scope of the remedial action to include stabilization of the upland soil. A proposed schedule with additional proposed design, stabilization study, permitting, and sampling, along with a proposed schedule, also was included in the report.

The EPA and NJDEP commented on Addendum No. 1 on October 4, 2005. Recommendations from the comment letter included the submittal of an interim stabilization measure work plan, which provided details of the final delineation activities, final design, mix design, and quality assurance/quality control (QA/QC) requirements, as well as the proposed long-term inspection schedule for SWMU 52

Final delineation/design sampling was completed in December 2005 and reported in the *SWMU 52 ISM Work Plan* (DuPont, January 2006). The work plan includes a summary of the statistical analysis of the field screening XRF data and the remedial boundary determination. Final design plans were also submitted in the ISM Work Plan.

The ISM actions that were selected for SWMU 52 included the following:

- Minimize the potential migration of the metals to the environment by removing the agglomerated material. The agglomerated material was a historical remnant of the former burning ground that has acted to stabilize the shoreline from erosion, but was found to be a potential source of metals to surface water and the environment. The ISM included removals of the agglomerated material fill material, and sediments above the A/B confining unit. In the sub-tidal and intertidal zones.

- Remove contaminated sediment within the footprint of the historical burning ground area adjacent to the agglomerated material. Riprap was installed to replace the agglomerated material and was installed to protect the completed shoreline from erosion.

- Minimize the potential of lead migration to the environment in the upland area by the in-situ stabilization of approximately 2.5 acres of non-native fill. The in-situ stabilization was completed from ground surface to depths averaging 4 feet but up to 10 feet where lead concentrations exceeded 400 ppm using XRF screening data. The migration of lead was accomplished by decreasing the hydraulic conductivity by approximately 2 orders of magnitude compared to the surrounding native soil.

- Maintaining administrative and deed restriction controls

The ISM activities – including the stabilization study, work plan submittal, and permitting – was started in the 1st quarter of 2006. Field activities began in the latter half of 2006 and are expected to be completed by the end of 2006 or in the 1st quarter of 2007. DuPont is planning to submit a SWMU 52 ISM report which will be designed to comply with the Chambers Works Hazardous and Solid Waste Act (HSWA) permit and the NJDEP Tech Regulations, and to satisfy the conditions of all the required permits.

Since this area is currently undergoing remediation, no further evaluation of this area is necessary in this PAR.

20.2.16 SWMU 54 (Solvent Recovery Units) (Plant 2)

SWMU 54 is approximately 1.7 acres and is identified as the area of the former Carneys Point Works where solvents were recovered. The solvents were reclaimed as part of the daily operation of the nitrocellulose and smokeless gunpowder manufacturing operations using a colloidal process. All that remains of this SWMU are two long building foundations.

SWMU 54 was investigated as part of the Phase I RFI. Results indicated detections of methanol and ethyl ether, but these concentrations were well below health-based screening concentrations. No nitrocellulose, nitroaromatics, nitramines, or ether- and alcohol-related SVOCs were detected. All detection limits were less than the NRDCSCC. DuPont requested a conditional NFA with deed restriction for SWMU 54. This SWMU was evaluated in the BEE. Results from the evaluation indicate that no COPECs were identified. Therefore, no further evaluation is needed. Based on there results, no further action is recommended for this SWMU.

20.2.17 SWMU 60 (Drum Disposal Area)

SWMU 60 was discovered during a 1995 field survey that identified the rusted hulks of several 55-gallon steel drums along a berm. The drums were corroded and crushed, but no visual evidence of liquids in or surrounding the drums was present. The drums were removed, and an investigation indicated that all metals concentrations detected were below the NRDCSCC. Several PAHs were detected above NRDCSCC at three locations. DuPont requested a conditional NFA with deed restrictions for this SWMU. More recently, this SWMU was recommended for further evaluation as part of the ecological investigation. Because this SWMU is being further evaluated as part of the pending ecological investigation, no further evaluation is necessary as part of this PAR.

20.2.18 SWMU 61 (Disposal Area II)

SWMU 61 is located in the northern portion of Carneys Point. This unit was identified as a disposal pit on the 1967 map of Carneys Point. Based on a design and operational data search, SWMU 61 was used to dispose of laboratory-quantity samples from the Carneys Point Development Laboratory and the Explosive Hazards Laboratory. Based on interviews with DuPont retirees, some of the chemicals disposed of in SWMU 61 were hydrochloric acid, caustic soda, benzene, and acetone. This activity started in the 1930s and continued into the 1960s. The SWMU is located directly adjacent to a ditch that runs into Bouttown Creek.

SWMU 61 investigation results indicated that metals were the only constituent concentrations identified above the NRDCSCC. DuPont proposed a conditional NFA with deed restrictions for this SWMU. More recently, this SWMU was recommended for further evaluation as part of the ecological investigation. Because this SWMU is being further evaluated as part of the pending ecological investigation, no further evaluation is necessary as part of this PAR.

20.3 Pathway Analysis

The following pathway analysis was performed in accordance with the methodology described in Section 3.7.1. Although no SWMUs warrant a pathway analysis for the Carneys Point FA, the entire focus area was subjected to further evaluation. This conclusion was based on the historical area review, aerial photograph evaluation, review of existing data from various media, review of historical investigations, and review of existing remedial documentation. This section provides the information that was collected and discusses the evaluation that was conducted.

This pathway analysis used, to the extent possible, the existing environmental data in accordance with the NJDEP Technical Requirements. Relevant tables are provided in the CD in Appendix D.

- ❑ Chemical Process Database: No chemical process data were available for review during development of the chemical process database.
- ❑ Buildings, Trenches, and Utilities Review: The GIS Building layer, Ditches/Trenches/Outfalls layer, and the Utilities layer were reviewed for this focus area. Only the 1919 and 1977 building plant layout maps were available for review. These plant layout maps did not specify the locations of many underground pipes, trenches, or ditches. However, the man-made drainage ditches are visible based on the expression of topographic relief on both plant layout maps.
- ❑ Soil Data: Soil analytical data were available for review from sampling completed as part of the RCRA RFI and ISM processes. Appendix D presents soil data results as compared to NRDCSCC and IGW criteria. SWMU 52 data were discussed in previous reports as part of the ISM characterization. SVOCs detected throughout Carneys Point include benzo(a)anthracene, benzo(b)fluoranthene, benzo(a)pyrene, benzo(k)fluoranthene, and dibenz(a,h)anthracene. Various metals

exceeded criteria in soil throughout Carneys Point. Soil sampling locations are shown in Figure 20-4.

- Sediment Data: Sediment analytical data were available for the Carneys Point FA for sampling completed as part of the RCRA RFI process. Appendix D presents results of sediment data collected in Henby and Bouttown Creeks during the RFI activities. Further evaluation of Henby and Bouttown Creeks will be completed during the ecological investigation. Sediment data are shown in Figure 20-5.
- Surface-Water Data: Surface-water analytical data were available for the Carneys Point FA from sampling completed as part of the RCRA RFI process. Appendix D presents results of surface water collected in Henby and Bouttown Creeks during the RFI activities. Further evaluation of Henby and Bouttown Creeks will be completed during the ecological investigation. Surface water data are shown in Figure 20-6.
- Groundwater Data: As shown on Figure 20-7, shallow groundwater in the Carneys Point FA flows from north to south because of the influence of the IWS pumping wells. The groundwater flow and impacts in the deeper aquifers are discussed on a site-wide basis in Section 4.

  Groundwater analytical data for this focus area are provided in Appendix D for the active A and B Aquifer wells. Additionally, because the BC clay layer is missing in some areas within Carneys Point, and the C Aquifer is under pumping conditions, the B and C Aquifers are considered to be strongly connected within this focus area. Therefore, C Aquifer well analytical data also were reviewed during this evaluation. Active and abandoned well locations are shown on Figure 20-7.

  Most of the groundwater data reviewed was collected and analyzed during the Phase I, II, III, and IV RFI reporting. Additionally, in compliance with the NJPDES-DGW Permit No. NJ008347, groundwater quality in wells located around the perimeter of the site is monitored. The wells in this program in the Carneys Point FA include monitoring wells S32-M01B, R31-M01B, O26-M01B, and K18-P01B. Many shallow wells surrounding the Secure C Landfill are monitored for both operating permits and closure permits. Data concerning the C Landfill were not reviewed as part of this evaluation because data are collected semi-annually, evaluated statistically, and reported in the DGW Report. In all, 110 data sets were available for evaluation and review from previously abandoned A, B, and C wells. A total of 103 data sets were available for evaluation and review from the C Aquifer active well list (which includes the B Aquifer where the BC clay layer is missing).
  Arsenic Pathway Analysis

In addition to the forward pathway analysis (including the chemical process data, history, and aerial photograph review), a backwards pathway analysis was completed for the Carneys Point FA using the metal constituent arsenic. Arsenic was chosen because it is ubiquitous across Carneys Point. Arsenic concentrations in soil and groundwater are presented in Figure 20-3 and 20-7.

20.4 Summary of Recommendations

Based on the pathway analysis, the following is recommended for the Carneys Point FA:

- Further evaluation of the vertical groundwater transport for mobile metals is currently underway within the SWMU 45-2 area as part of the Phase IV RFI Supplemental Work Plan (DuPont, 2005).
- Further evaluation of the following SWMUs and areas of interest will be completed as part of the ecological investigation outlined in the BEE (DuPont, 2006):
  - SWMU 52: Debris Disposal Area
  - SWMU 42: Henby Creek
  - SWMU 60: Drum Disposal Area
  - SWMU 45-9: Carneys Point Former Process Drainage System
  - SWMU 45-2: Carneys Point Manufacturing Area 2
  - Two surface water bodies identified as “acid fume ponds”
  - Portions of Bouttown Creek adjacent to SWMU 45-9
  - Tidal basin between Bouttown Creek and Helms Cove

21.0 CONCLUSIONS AND RECOMMENDATIONS

A comprehensive GIS and associated database were developed for the DuPont Chambers Works Complex and were used to perform the Preliminary Assessment described in this report. The GIS serves as the information warehouse containing site-specific data and related information including site infrastructure, process histories, natural physical features, subsurface geology, hydrogeology, and environmental analytical data. Use of this GIS tool enabled a more comprehensive evaluation of the entire Chambers Works Complex than could be achieved previously, focusing on identification of potential source areas and migration pathways. Evaluating information as part of the diligent inquiry, along with use of the GIS tool, led to identifying potentially contaminated areas of conerns (AOCs). Additional investigations in the AOCs are recommended to confirm the presence of suspected sources and the potential effects of those features on groundwater, surface water, and sediment.

21.1 Historical Overview

Operations at the Chambers Works Complex spans a history of more than 110 years. Manufacturing began in 1894 with smokeless gunpowder to support the war effort and was quickly diversified over time. Based on the manufacturing history, the site can be considered as two distinct areas: Carneys Point and the Chambers Works manufacturing area.

The Carneys Point area was solely used in the manufacturing of explosives. Although a variety of explosives were manufactured over time, the chemical compositions are well documented. Buildings were spread out, and minimal infrastructure (utilities, ditches) was present. Production continued until 1978. The buildings were razed, and the area has since been idle.

The Chambers Works manufacturing area was the center of research and development as well as manufacturing for a wide range of products using an even greater variety of chemicals (primarily VOCs and SVOCs). Manufacturing and support buildings were constructed and frequently converted to meet the needs of production. The infrastructure originally consisted of earthen ditches to which liquid wastes were likely diverted. Before existence of relevant environmental laws and regulations, waste was also managed on-site with the use of burning areas and landfills.

Even before the existence of relevant environmental regulations, DuPont was proactive in implementing corrective measures. In 1970, DuPont installed a groundwater IWS to contain groundwater on-site. As environmental regulations promulgated, DuPont took the steps necessary to be in compliance. Under the RCRA program, DuPont has completed four phases of the RFI and has completed a number of interim measures. Over the past 15 years, significant resources (more than $150 million) have been spent to investigate and remediate areas of the site. Much of these expenditures were projects initiated by DuPont and were facilitated by the cooperative working relationship with the NJDEP and the EPA.

The long-term remediation program and accompanying schedule developed by DuPont represents a commitment to continue a comprehensive program for the site. Consistent with this commitment are the following:

- Evaluation of potential discharge of contaminated groundwater and surface water to the Delaware River and its tributaries
- Identification of significant sources to groundwater and surface water
- Evaluation of the feasibility of remediating those significant sources
- Optimization of groundwater recovery
- Enhancement of groundwater monitoring

The PA was primarily conducted to meet the second goal.

21.2 Preliminary Assessment Strategy

This report also summarizes the CSM developed using the GIS tool that was created for the site. The revised CSM was presented both on a site-wide scale as well as for each focus area of the site. The findings of the PA were presented using the GIS-based CSM, and potential areas of concern were identified. For areas of the site where data gaps were identified, recommendations for filling those data gaps were provided.

The objectives of this assessment were to meet the NJDEP requirements for a PA and answer the following questions:

- What are the historical site conditions and practices that may have resulted in releases to the environment and what constituents are likely to have been released?
- What are the pathways through which constituents may have been or are transported into environmental media (receptor media)?
- What are the potential impacts of these constituents on receptor media?
- What additional investigations are needed to evaluate the presence and/or effects of known or potential historical sources?

As described in Section 3, the assessment of potential sources and receptor media described in this report was performed using a step-wise approach which included developing a comprehensive GIS — including an accompanying database of site analytical data, historical process information, and spatial data — that could be used as an investigative tool. This investigative tool was used for all areas of the site, including areas not previously designated as SWMUs or AOCs under the RCRA CA program and the ACO with NJDEP (1984, 1988).

21.2.1 Focus Area Evaluations

Based on an understanding of the site history, the site was subdivided into 16 FAs that roughly defined areas with similar histories (such as manufacturing processes and waste disposal practices). Based on additional research, sub-areas were defined within some of the FAs. With the use of the GIS tool, aerial photographs, site maps, process histories, and analytical data were analyzed to identify potential sources for groundwater, surface water, and sediment. The potential sources identified that are not already being addressed by ongoing remedial investigations, such as the SWMU 8 Corrective Measures Study, include the following:

- Fifteen historical outfalls along the Delaware River and Salem Canal.
- Potentially impacted soils due to a historical petroleum tank farm.
- Former loading/unloading areas, storage areas, and a pond.
- Areas where there were numerous process buildings with a clustered network of ditches and building trenches.
- Process waste sumps associated with former outfalls
- An area where there was a 100,000-pound release of ortho-chloronitrobenzene in the 1980s
- Soil present in an area that historically was part of the basins area and which is known to have elevated concentrations of site-related constituents
- Sections of the historical process wastewater ditch system
- Soil beneath and in the vicinity of previously remediated process wastewater ditches, and potentially subsurface DNAPL, which could be acting as a source to groundwater.

21.2.2 Site-Wide Evaluation

As a result of the detailed historical and analytical data review performed as part of this PA, the boundaries that define different process areas were refined from the original FA boundaries. Based on this refinement, and considering areas at the site that require additional investigation, 11 AOCs were defined:

- AOC 1: Fluoroproducts
- AOC 2: TEL
- AOC 3: Jackson Labs
- AOC 4: Aramids
- AOC 5: Historical Basin Footprint and Ditches
- AOC 6: Dyes
- AOC 7: Elastomers
- AOC 8: Warehouse, Transport and Construction
- AOC 9: Monastral
- AOC 10: White Products
- AOC 11: Former Drainage Ditch

The site-wide evaluation also integrated the potential sources and migration pathways identified in the individual FAs to develop an updated conceptual site model. The primary features of the updated conceptual site model are the identification of new potential sources and, significantly, the precision of the CSM that has been established as a result of the GIS system. For example, although contaminant sources already were considered more likely in areas with higher production rates, buildings, and a network of ditches, these areas have been identified precisely by digitizing site maps and aerial photographs. This aspect of the upgraded CSM (i.e., the GIS tool) will help future investigations to identify more accurately the locations of sources (by enabling confirmation of potential sources through sampling at precise locations) and therefore help achieve future remedial actions more rapidly and effectively, where necessary. Similarly, the locations of historical outfalls have been mapped and, therefore, will be used as the basis to define the sediment sampling program as part of the perimeter investigation.

21.3 Recommendations

DuPont recommends additional investigations across most of the Chambers Works manufacturing area. In some areas, however, other investigations or remedial measures are currently underway, so additional investigation in those areas is not recommended based on the findings of this PA. For example, SWMU 8 was not designated for additional investigations because characterization is complete and a Corrective Measures Study is underway. Similarly, Carneys Point was not designated for additional investigation in this PA because investigations are ongoing there or will be performed as part of a separate ecological investigation.

Within a particular AOC, the recommended investigations may include groundwater sampling/monitoring, soil sampling, or a combination thereof. Details regarding the recommended investigation(s) for each AOC are shown in Figure 4-4 and are designed to meet one or more of the following objectives:

- Evaluate B Aquifer groundwater quality downgradient of potential sources in areas of the site where insufficient data exists. Assessing groundwater quality in these areas will help to determine whether an area is (or was) a source to groundwater.
- Increase spatial characterization of B Aquifer hydraulic gradients near the site perimeter to confirm hydraulic containment by the IWS.
- Further refine understanding of potential groundwater to surface-water pathways by installing additional perimeter monitoring wells.
- Evaluate soils that may be acting as sources to groundwater by further characterizing the distribution of elevated concentrations.
- Evaluate sediment quality in the vicinity of historical process wastewater outfalls along the Delaware River or Salem Canal.
- Further evaluate soil, sediment and surface water quality in Carneys Point as part of the Ecological Risk Assessment for Carneys Point.
- Refine the location/boundaries of several SWMUs based on review of more accurate aerial photographs and GIS data.

Additionally, sampling of Delaware River sediments that may contain site-related constituents as a result of historical outfalls is recommended.

Specifics about the number and locations of sampling and monitoring points are not presented in this PAR. All sampling will be completed in accordance with the appropriate section of N.J.A.C. 7:26E. After receipt and incorporation of agency comments on this PAR, a work plan for the additional investigations associated with the site perimeter will be submitted, followed by a work plan for additional investigations associated with the interior of the site.

62	Aramids/Nitrators Sump	*No further action for soil recommended in Phase III RFI.*			
63	Azo-Dye Area	Further investigation for this SWMU to be completed as part of the Phase IV RFI Supplemental Work Plan.			

KEY:

- SWMUs sampled in Phase IV
- SWMUs sampled in Phase II or Phase III RFI and recommendations
- SWMUs that have received NFA
- SWMUs where work is complete
- SWMUs covered under another regulatory program
- RCRA SWMUs that require groundwater monitoring
- Area improperly identified as SWMU
- EPA correspondance - Closed or RCRA Clean Closed
- Ongoing correspondance with Agency for final remedy

* Biennial Report submitted 8/06
COPECs - constituents of potential ecological concern

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc. (EDR). The report meets the government records search requirements of ASTM Standard Practice for Environmental Site Assessments, E 1527-00. Search distances are per ASTM standard or custom distances requested by the user.

EXECUTIVE SUMMARY

DATABASES WITH NO MAPPED SITES

No mapped sites were found in EDR's search of available ("reasonably ascertainable ") government records either on the target property or within the ASTM E 1527-00 search radius around the target property for the following databases:

FEDERAL ASTM STANDARD

NPL - National Priority List
CERCLIS - Comprehensive Environmental Response, Compensation, and Liability Information System

FEDERAL ASTM SUPPLEMENTAL

CONSENT - CONSENT
ROD - ROD
Delisted NPL - NPL Deletions
HMIRS - Hazardous Materials Information Reporting System
MINES - Mines Master Index File
NPL Liens - NPL Liens
RAATS - RCRA Administrative Action Tracking System

STATE OR LOCAL ASTM SUPPLEMENTAL

NJ PF - Publicly Funded Cleanups Site Status Report
CHROME - Known Chromate Chemical Production Waste Sites

EDR PROPRIETARY DATABASES

Coal Gas - Former Manufactured gas (Coal Gas) Sites.

SURROUNDING SITES: SEARCH RESULTS

Surrounding sites were identified.

Elevations have been determined from the USGS 1 degree Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified. EDR's definition of a site with an elevation equal to the target property includes a tolerance of +/- 10 feet. Sites with an elevation equal to or higher than the target property have been differentiated below from sites with an elevation lower than the target property (by more than 10 feet). Page numbers and map identification numbers refer to the EDR Radius Map report where detailed data on individual sites can be reviewed.

Sites listed in ***bold italics*** are in multiple databases.

Unmappable (orphan) sites are not considered in the foregoing analysis.

FEDERAL ASTM STANDARD

CORRACTS: CORRACTS is a list of handlers with RCRA Corrective Action Activity. This report shows which nationally-defined corrective action core events have occurred for every handler that has had corrective action activity.

A review of the CORRACTS list, as provided by EDR, and dated 04/20/2000 has revealed that there is 1

EXECUTIVE SUMMARY

CORRACTS site within approximately 1 mile of the target property.

Equal/Higher Elevation	Address	Dist / Dir	Map ID	Page
ATLANTIC ELECTRIC DW STATION	***373 N BROADWAY***	***1/2 - 1 SSW***	***B637***	***1158***

STATE ASTM STANDARD

SHWS: The State Hazardous Waste Sites records are the states' equivalent to CERCLIS. These sites may or may not already be listed on the federal CERCLIS list. Priority sites planned for cleanup using state funds (state equivalent of Superfund) are identified along with sites where cleanup will be paid for by potentially responsible parties. The data come from the Department of Environmental Protection & Energy's Site Status Report.

A review of the SHWS list, as provided by EDR, has revealed that there are 3 SHWS sites within approximately 1 mile of the target property.

Equal/Higher Elevation	Address	Dist / Dir	Map ID	Page
EXXON SERVICE STATION PENNSVIL	RTE 49 / LIPPENCOTT A	1/4 - 1/2 S	634	1157
